1. Instructions for MFJ 940 Tuner?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-14 00:00:00 UTC
From: ed <ewindes@my-deja.com>
Message-ID: <8n9l6g$h21$1@nnrp1.deja.com>
Source record: 182669

Anyone able to give me a quick summary of how to adjust this tuner?

I understand the Transmitter/Inductance/Antenna adjustment - and how
adjust during recieve for maximum signal.

I don't understand how to adjust the "Power" knob (which pulls out in
addition to rotating) and how to read SWR/Power off the meter.

Thanks...

I think it'd be easier to use a coiled line. Comes to that, that's what the commercial folks do. But I KNOW a quarter wave stub worked for my 2 meter, 3/4 wave mobile antenna back in 1970.

In a real antenna there's non-zero current at the connected point. This may well be enough to excite a tank circuit. End effect is increased by the tank's parasitics. Even if this is not enough, you need only shorten the dipole a little to put the zero current point inside the tank circuit resonator. Think of it as shunt feeding the tank.

OK...the discussions I've seen here (and been a part of) have offered various explanations about what's going on, or what people think is going on. (Or what people know MUST be going on! :-) How about some _measurements_? HOW do you know that the quarter wave stub worked? HOW does W8JI know that a coil with a perpendiular quarter wave wire attached to its center tap works, but that the same antenna minus the quarter wave wire does not give the desired collinear results? Are there simple measurements that are within the reach of many hams that will give the answers? What measurements, ideally simple ones, would suffice to convince you that proper collinear operation was (or was not) achieved? (I think the answer is yes, there are some reasonable measurements, but would like to see what others think would be reasonable tests to actually do.)

A stub is capable of doing the job but a tank is not, unless the components are so large physically as to have considerable capacitance to the environment.

> Once this is done, current flows (for example) TOWARDS
> the right-hand end of the left side dipole and AWAY from the left end of the right

> wanted.

This does get confusing. Rather than presupposing what does and doesn't work for the phase inverter, let's take a look at what relationships are needed for the desired voltage and current relationships to exist. A complex structure containing several half waves of wire in addition to lumped resonant circuits is likely to support several modes, some of which are desirable and some of which are undesirable and may need to be explicitly suppressed.

Consider the same two element collinear antenna system as above except one element is above the other. The thread opened with a question specifically regarding vertical collinears so I think it makes sense to stay on track. The differences are immaterial as far as this discussion goes.

Assume the two elements have approximately equal radiating currents and are phased for optimum broadside gain. Arbitrarily choose a phase reference so that the voltage at the top of the lower element is positive compared to the bottom.

Further assume the current and voltage distribution is dominated by the familiar standing wave pattern characteristic of 1/2 wl dipole antennas. This is a reasonable and useful assumption and can be justified later if anyone cares.

The voltage polarity of the upper antenna will be such that the voltage at the highest part will be positive compared to the voltage at the lower end. In other words, the voltage phase will be the same for the both radiators.

As a simplifying assumption, assume that if the voltage (potential) distribution is the same on both elements, the current distribution will also be identical. Identical current distributions, or at least identical phase at the current loop, is the condition for maximum broadside gain.

The final assumption (for now) is that comparable power will need to be delivered to each element by the feed system.

If the voltage and current are known, power can be calculated: P = E * I where E and I are the voltage and currents expressed as phasors. For the present purpose we can assume the phases are either 0 (+) or 180 degrees (-).

Consider a three terminal 'black box' device connected to the top of the lower radiator, the bottom of the upper radiator, and to an imaginary virtual ground.

What direction must the current flow from the lower element into the block box in order for power to flow out of the lower element and into the black box?

What direction must the current flow into (-outof) the black box from the upper element in order for power to flow out of the black box into the upper element?

According to Kirchoff's current law, the current flowing from the virtual ground will be the algebraic sum of the other two currents. Assuming the other two currents are of the same magnitude, will they add or cancel? If the two currents cancel, then the virtual ground may be disconnected and the 'black box' device becomes two terminal. If the currents add, then the third terminal is _required_ for proper operation and something different from a two terminal LC tank will be required for the phase inverter.

sideband,
Actually, the input impedance of a 1/2 wave dipole that is
put up in a 'flat top' configuration is around 70-78 ohms. If
you fed this with 50 ohm coax, the SWR would be about 1.5:1.
The easiest way to match impedances is to let the legs of the
dipole 'droop' a little bit. The legs being slightly closer
together, and nearer to ground than the feed point, lowers the
input impedance. Most people call this an inverted 'V', but
it really isn't.
'Doc

You may think I'm kidding, but the CBer down the road (11 miles
fortunately) has just such a ground system.

He also has the aluminum pie plates on his feedline (for lightning
protection) , and a chrome plated loading coil on his Chevy Suburban.

Please don't disapoint me, and tell me everything I've learned from
his is wrong! He is even installing a "Smoking Joe Gun" fractal shaped
addition to his CB antenna because it talks something he calls
"fatside" when he is mobile.

I haven't figured out what fatside is, but it probably has something
to do with his "back door", which he says makes him ten ate now that
it is plugged up.

It all starts with a tiny little radio, and ends up with a 4CX10000.
He put toilet floats on his element tips to prevent "fire" he says.
All of this is grounded in a water jug filled with salt water, sitting
on his basement floor.

I was going for the vertical dipole idea, as opposed to the horizontal.
I'm going for an omnidirectional antenna, here, and going horizontal
would make me directional perpendicular to the line of the antenna.
Considering most of the "skip" here comes from the south, and the only
available wall I could put a horizontal dipole on would face east, that
would be a bad thing.

It isn't having current that is the problem with the tak, it's what
the tank looks like as a two terminal network. It looks nothing at all
like a stub, which because of it's physical area can look like three
terminals!

You need three terminals to invert phase in a small physical area. You
can shift phase 90 degrees or less (like a high value of series
reactance driving a low resistance load), but you can't invert it
without some sort of third connection.

Think about that for a while, and I think you'll see my point.

There is absolutely no way a resonant circuit can work. All it would
be is a pure series resistance, or series reactance with a series or
parallel resistance.

Hi, Doc:

You said that antenna efficiency does not vary with power applied.

I replied that the efficiency of an antenna built with PTC resistors would vary in the opposite direction, with power input, from an antenna built with NTC resistors.

'Why' was not my point -- which was simply that efficiency could be made to vary with power applied. That's all.

Methinks thou hast upgefucked. There is no such model tuner in the MFJ arsenal, unless it is some hopelessly out of date model - not that the old ones don't work just as well as the new ones.

>I understand the Transmitter/Inductance/Antenna adjustment - and how
>adjust during recieve for maximum signal.
>
>I don't understand how to adjust the "Power" knob (which pulls out in
>addition to rotating) and how to read SWR/Power off the meter.

Any reference to Power or SWR is a reference to sending a signal OUT - in other words, TRANSMITTING. I have to wonder whether or not you are licensed for that, since licensed operators usually put their callsigns into their posts

If the knob that you refer to as the "Power" knob is what it used to be on some earlier tuners, it was the means of calibrating to full scale on a forward power setting so that when you measured the reflected power it would show up on the meter as SWR. This was before the advent of the twin needle meter, which made all those steps unnecessary.

I just downloaded Richards Eznec file and ran it on my computer. I had just started to build the K2, believing Chip's site and info presented there. On seeing the Eznec file, I will use the wire for something else. I am no expert but I can see that better and simpler designs are easily possible. I like to build and experiment with antennas and I am amazed at the amount of anecdotal evidence that is presented to hams by hams. I run mainly QRP and always try to get the most efficient design I can. I use Eznec and TLA to optimize my antenna designs and feed methods. It always amazes me at the number of hams who are running 100 watts out but loose much of that power in they're feedlines and matching networks. They are actually running QRP and just don't know it!! It seems to me, and this is only my opinion but Chip seems to be in this catagory of anecdotal evidence and half truths. I guess I will be the next one to be sued. But we in the ham community need to produce better information and stay away from the "it worked great for me " syndrome.

Source record: 182689

In the case of a 34 wavelength (1/2 over a 1/4 wave) collinear, if the stub doesn't work, you get a nasty null in the pattern. That's pretty noticeable on 2 meters. Still, it's hard to retroactively measure the thing. Heck, if my Time Machine works, likely anything else I build must, too, right? (g!)

However... there must be more than a few stub-phased collinears out there, and someone must have real-world recent measurements on 'em. maybe one of those someones will pipe up.

check a local hardware, building supply or surplus.

I have mine delivered out of Denver.
I have to buy 400 to 500 lb at a time.
The angle comes in 25 foot lengths.
the 3/8 rod is in 12 foot lengths.

That is how I can sell the antenna so cheap.

Well, Tom, if getting small kills it, then a sufficently coiled up stub should suffer the same ills, being a small resonant circuit as well. I think, however, that they've been enough used that SOMEONE would have discovered if they didn't work. I admit I haven't done a
lot of looking into the subject!

Hmm. (thinking out loud). In the collinear, there is another capacitance element, from the tank to the fed (exciting) dipole, and from the tank to the connected dipole. Would that be enough?

Richard- Chip has just posted (on the egroups list) a defense that
although the K2 has negative gain, it is about 2 dB better than a
shielded dummy load. I assume this means it is not worthless, after all.

I am reminded that Kurt N. Sterba claims to have worked a contest using
two grocery carts back-to-back, as a dipole.

Model that!

Hi Bill,

I don't challenge the claim of the k2 besting a dummy load, I'm sure that this is accurate. As you might note however, those two grocery carts may easily best the k2 and is probably faster on rotation too.

;-) Model a grocery cart? Show me a picture and I will pirate the wire list by tracing its silhouette from the screen. ;-)

I don't know about the HS-1500 MkII (could be a typo on your part...)
but I have had the HS-1500 installed on a Toyota p/u for quite a few
years now, and wouldn't hesitate to recommend it. Just make sure you
get all the body parts of the vehicle connected together using wide
braided straps, and check these connections frequently, to make sure
corrosion hasn't affected them.

Sign me as a satisfied customer of High Sierra Antennas, happy to give
the recommendation.

Hi Cortland,

Cortland Richmond wrote:
>
> Well, Tom, if getting small kills it, then a sufficently coiled up stub should suffer the
> same ills, being a small resonant circuit as well.

That's correct. The trick is that the stub is perpendicular to the primary radiating elements and is resonant for the common mode. The combined effect of 1/4 wl resonance in both the differential and common mode is to make the stub appear as a 1:1 autotransformer with a grounded center tap. Coiling up the stub will spoil the 'virtual ground' provided by the common mode resonance and adversely effect the polarity of the current phasing on the upper element.

> I think, however, that they've been
> enough used that SOMEONE would have discovered if they didn't work. I admit I haven't done a
> lot of looking into the subject!

There's all sorts of stuff out there which fails to meet advertising claims. I suspect the success of the technique in UHF mobile antennas has far more to do with elevating the radiator above the clutter than actual collinear gain. The benefit of height can easily outweigh the partial null on the horizon resulting from improper phasing.

I wouldn't worry too much about a dipole being directional. Unless
it is higher than 1/2 wave length above ground, it has an
omni-directional
pattern. The pattern also depends on surrounding objects
(distortion).

I think Dwight might be referring to problems caused by the poor
bypassing and lead routing that is common today in radios.

One example is in the key jack. My IC-751A doesn't ground the keyjack
at the chassis, instead the ground lead and everything bypassed has to
follow a path all the way to the circuit board where the keyer chip
is.

Audio systems do the same, although in some radiaos they wisely have
the RF bypasses grounded through a less lengthy path.

Grounding the case of the radio can help eliminate common mode
excitation causing the accessories connected to the radio from feeding
RF into the non-grounded jacks, like audio and keying input lines.

Why the radios are grounded that way internally, instead of using the
chassis or cabinet entrance points as a common ground point, is beyond
me. It must be because it's easier to insulate a jack and a tiny PC
board on a jack than isolate the signal input on a complex circuit
board, or they've never bother to learn how to work with ground loops
properly.

It amazes me they even pull that nonsense with a dc control signal
that has a two or three volt threshold, like the keying line inputs.
On my test radios that are subjected to high RF fields, I rewired
everything and grounded all the shields and jacks at the inputs where
the leads first enter the radio.

For a 200 watt CB transmitter, you HAVE to use 2 gauge wire. You also
need a better ground system. Silver or chrome plated wire is best.

A jug of saltwater (like an old water cooler jug) with the bottom
filled with old pennies and ground wires run through the cork works
well for a portable salt-water ground, and will give a huge signal
increase.

With conventional 5 watt CB's and 100 milliwatt to 500 watt or larger
amateur installations, the rules are different.

That's because the amateur equipment operates on another BAND that
doesn't restrict the flow of current and voltage as much as CB, and
can comfortably use almost any gauge or type of wire (alsthough copper
or siver plated copper is best). 5 watt CB transmitters will work
perfectly well following the same guidelines.

For amateur bands and low-power CB use, the salt water portable ground
would not be adequate. You need an outside ground or counterpoise
system of some form, used in conjuction with a safety ground.

Many people don't realize about the gyro-rotational effect of charges
in the 27 MHz band. Thats why diathermy and ISM devices are allowed on
27.120 MHz, and why when a CB runs more than five or ten watts none of
conventional antenna and grounding theory applies. I even share a
patent for a medical device operating on 27.120 MHz, and I'm the
engineer who developed a few dozen devices patented by medical
companies in that frequency range.

47. NC Bloviates about the NG and its denizens

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-14 00:00:00 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <bKTl5.14323$H14.32608@newsfeed.slurp.net>
Source record: 182779

NC:

What *would* lead in some way for you to contribute to a new chapter in the history of this NG, by simply leaving it?

Would you consider entering democrat politics, where your desires to demonize the holders of opposing opinions, and your tiresome bloviations about vast conspiracies and victimhood, would probably find an eager audience?

Can we help you find your way out, pls?

Why would a person such as yourself want to subject himself to the milieu you describe?

Take your own excellent advice.

Stop reading the materials here.

Stop contributing to the NG here.

Go away to the dot-com you have created and stay there.

We here have enough intestinal and other fortitude to do without your contributions.

We do not wish you ill.

We wish nothing more than for you to get out, stay out, and don't come back.

Is there any part of 'get out, stay out, and don't come back' that you do not understand?

If so, ask your attorney to explain the phrase.

Take fill dirt, the Zero Knowledge Transferable character, with you.

K3BHJ
****

NC bloviated, in part, somewhere, about this NG:

Copyright violation; impersonation; libel;prevarication about proper copyright
and pending patent notification; misleading and incorrect assessment; and so on
will NOT lead in any way to my leaving this NG.

If you do not wish to read the materials, then don't.

What has resulted from this abuse is a new and global interest in exactly the
kind of mischief that has been promulgated here. I will actively assist any and
all scholars, legal types, and press who want to investigate this active
attempt to destroy a new technology and the inventor and company that go with
it.

To my knowledge, this is a new chapter in the history of the internet.

> NC

The biggest problem is you have NO knowledge of the internet.

Rather than "new and global interest", you are nothing more than yet another
self righteous ass. Your ilk has been seen MANY times before on the internet
and the Arpanet before it. No one particularly cared about the others and
no one particularly cares about you. You are like a little annoying bug
that keeps buzzing around one's head; nothing of substance and a minor
annoyance.

Get a clue; Al Gore didn't invent the internet and you are just another
whinner.

You forgot to mention the aluminum pie plates on the coax for lightning protection, and the fractal reflectors to give the antenna a truly isotropic pattern. If you're going to have a 200 watt C.B. antenna you should go first class.

Hi Bill,

The riposte about comparison was not meant to be literal. As you've
pointed out there exists no publicly available evidence to the
contrary.

You may be surprised to not see the typical knee-jerk response,
because I carefully and dutifully insured that ALL results conformed
to published characteristics.

Well, I've got to admit I didn't do a perfect job, I improved the
design (and by only fumbling around too!). You will find no
contradiction of my results, the only reaction will be embarrassment
in that the design NEEDS loss to offer these wonderful

characteristics. That I improved the product necessarily proves that my replication is MORE lossy than the original, but if we are giving benediction to dogs, then mine must be the pope by now.

;-) One consequence of this improvement is that it happened without recourse to the standard methods employed by practitioners of the craft (or they would have done it themselves - in other words it was not "obvious" to them). As such, and given there is an improvement (a critical characteristic to the Patent Office), it is obvious that it is patentable by me within one year of last weekend. To all others, this becomes "prior art."

However, in the spirit and to the letter of my offer made here roughly a year ago, I cede all but commercial rights to this design to the public domain. All parties may build their own model as long as they do not do so as part of a commercial interchange (no sales or commercial exchange is allowed). I expect certain commercial interests to violate this will, but they do so in jeopardy of legal consequences. Sorry gang, couldn't keep the levity from creeping in ;-)

Ok...

Now this is getting a bit silly...

Originally I asked a few questions about constructing an antenna.. Great. I got a couple responses that seemed to answer those questions. Again, Great.

Now people are posting simply to cloud the issue, and its not appreciated.

For those of you who tried to help, I send my thanks..

For the rest of you, who purposely tried to cloud the issue, I hope you enjoyed making fun of the CB'er. I had thought the original reason for HAM radio was to share knowledge through communication.. I guess I was wrong.

Move out.....seriously tho....you got a problem there. And yes a wire
antenna would work out well. The trick will be to hide it. I don't
know what you mean by "unreachable area".

Also can you run a whip on your car and drop a feedline to it? Just a
thought.

With what your saying I guess you will have to stick something out the
window in the middle of the night.

Is there anyway you could get access to the roof?

Richard- forgive me, but the Knee-jerk from the jerk has already happened. One of the few mistakes you have made is in applying logic to an expected reaction from the Chipper. He is above and beyond logic, because he is a law unto himself. Fortunately, being a law unto oneself only has legal standing in competency hearings.

I agree with all you say, and will be glad to stand up for the "prior art" and "improvement" and the "not obvious" parts of the situation.

Hi Bill,

Pirated material now is it? The correct vernacular for CEASE is
AVAST, no wonder that thread was meaningless.

;-) Yup, I stole it right off the screen of my display. I held a
page of paper over the image and transferred the design by eye. Of
course there were the usual obstacles put in the way (reversed
perspective components with bogus additions and such) so that my
efforts were frustrated in making an exact duplicate. I got the same
problem with my new twenties at the JiffyMart.

That did not seem to matter as far as modeling results go though,
except I improved some characteristics. As the EZNEC file I offer at
my page
http://www.qsl.net/~kb7qhc/antenna/fractal/n1ir/k2/index.htm
is a DIFFERENT design (there have been no proofs to the contrary); I
freely offer it to the world for non-commercial use. Those commercial
interests that violate this will, may find themselves without legal
protection. ;-)

Enough mirth and levity, everyone back into the pool.

73's
Richard Clark, KB7QHC

p.s.
reports to the contrary
http://www.qsl.net/~kb7qhc/antenna/fractal/n1ir/k2/index.htm
is still up and running with downloads to many happy parties.
Hope this helps :-)

Yes, the 12 gauge will easily handle 1500 watts, more actually. If you want sound antenna advice, post to the antenna group. There are some CBers that know what they are talking about but relatively few and the myths and misinformation abound.

Hi Bill,

The sense of the knee-jerk response would have been to burn down the
house to kill a fly in the living room. If there are any questions
with my data that conforms quite closely to the original, then the
original must suffer equally.

Quite a paradox isn't it (and yes, Bill, I know this is your point all
along)? To this point there has been no condemnation of the data.
The pressure to maintain the original afloat has created a dynamic
tension with the desire to sink the replica. Something akin to
splitting a siamese twin that shares one head. This is the long way
of saying my data is not going to be impeached (however, Bill, I'm
sure you would be willing to place odds).

For others wondering what all the folderol is about, a visit to:
http://www.qsl.net/~kb7qhc/antenna/fractal/n1ir/k2/index.htm
will reveal nothing but simple data. (Contrary to expectations, it is
still in operation and downloading the EZNEC file to happy
individuals.) Data nearly identical to the original, but in some
instances better. Those unfortunate souls seeking the heat of

controversy will probably be dumfounded by all the smoke in this forum.

And again, having been remiss, let me remind one and all once again: DO NOT RESPOND TO TROLLS.

Why do people keep getting this idea that I'm not using safety wire?
<:-))
I even explained about the turnbuckles on the current tower and told some
one how they go on.

Man, with an installation this size there are lots of things such as
watering down the guy anchors to get the dirt to flow back in around the
block to make them more solid. (before putting side pressure on
them--tightening the guys)

From: Cortland Richmond <Cortland.Richmond@usa.alcatel.com>
Message-ID: <399835AD.F3C51A0E@usa.alcatel.com>
Source record: 182801

A resonant wire longer than a half wave is not a constant current antenna; current flows in opposite direction each 180 degrees along the wire. This applies to the array of end-fed collinear dipoles.

Consider a two element collinear. Where there is a potential, as at the end of a dipole, current will flow in every case towards or away from that point identically in any wires connected to it (but less than a half wave away). In a long wire this produces current 180 degrees out of phase between adjacent half wave sections, which is less than efficient for directivity. Therefore, another 180 degree phase shift must be added between the dipole sections. Either a stub or a tank will do that. Once this is done, current flows (for example) TOWARDS the right-hand end of the left side dipole and AWAY from the left end of the right side dipole -- which is the same physical direction in both. This is what we wanted.

Cortland

Oh ya the antenna group. Been there lately? Bunch of children arguing about anything and everything. Couldn't take more than a week of reading that group. You probably will not learn much about antennas over there.

The original poster had a simple question about dipoles and the thread ends up with some dude using 2 gauge cable (bet you it's fun to work with!) and salt water and old penny grounding system!! Sounds interesting but kind of silly at the same time.

sideband,
Your answers;
1. Sure, no restrictions on making antennas.
2. Size of wire makes absolutely no difference as long as it
can support it's own weight.
3. Use 1/4w each side, making it a 1/2 wave antenna. This will
keep the input impedance at/near 50 ohms, and easier to match
a feed line to.
4. A dipole is 1/2 wave in length. Other lengths are called
doublets. (dipole = doublet, but doublet doesn't always = 1/2
wave.)

It sounds like it should work. Naturally, the farther an antenna is
from surounding objects, the better it works. Another point is that
the closer the antenna is to your house/apt. the more electrical noise
you will hear. Also means that you may 'get into' your/others
electrical
appliances. That's not a 'hard and fast' rule, but true most times.
Good luck...

sideband,
Efficiency of the antenna doesn't change with the amount of
power it's fed. Size of conductor makes no difference in power
handling ability at the power levels your speaking of.

Doc:

Thanks for this.

Another question, now... If the impedance isn't 50 ohms (how do you
measure this, anyway?) What would my options be to get it matched up?

TIA

Part of any N.G. is just debate and junk posts. Somewhere
through it all information does leak through. What else is new.
But, as for dipoles.. they come recommended, but don't use
string, rope or spagetti. The smaller the wire the higher the Q,
but in practice you want wire that is light, remember gravity
acts on every inch.

Feed a dipole with coax unless you have a tuner and plan a long
dipole perhaps for 75 and wish to operate it multi-band.

Tom W8JI,
Just wondering;
1.Which cheek are you using?
2.Does your tongue get tired?
3.Does the date of the pennies make a difference?
4.Should you use ordinary table salt, or 'sea' salt?
5.Do you have to clean the jug like an aquarium?
6.Would a pan under the jug (like the one under a leaking grid resistor) help?
7.I have some 6" drill stem pipe, can I run higher power with it?
8.(see #7) should I cap the ends to contain stray RF?
9.Did you take corrolis(sp) effect into concideration?
10.If you mount the antenna on a 'lazy-susan' do you get circular polarization?

>Cortland
>(ka5s@saber.net)

A tank certainly won't do it, because at resonance it appears as a
high value resistance. The electrical equiv of a resonant parallel
tuned circuit is a high value resistor. Above and below resonance, it
looks like a simple capacitor or inductor in parrale with a high value
resistor, or in series with a low value resistor.

If you ceneter tap the tank, and ground reference that point, you can
get push-pull voltages that will drive the next section.

Stubs work after a fashon, if configured correctly.

sideband a swr meter is how you measure if it is 50 ohms or not ... 50 ohms would be a 1:1.1 swr , 100 ohms would be a 2:1 swr as well as 25 ohms would be a 2:1 swr ... trim each end the same or add the same to each side to get your swr down to which every frequency is of your interest..

Hello here is the web site for Tom Mackays TGM MQ2, iam in the process of testing and using the MQ2 model in VK, it is the first mini quad of it's type i have ever had a go at,
and to be quite honest,i was very surprised on how great it worked,my reference antenna was a 4EL 6 Band Yagi a TET TE 46.by EMTRON
a great antenna even though it has traps,the MQ2 at it's worst .was only 2 S points down on RX/TX, and it was sat only 1/3 of the hight,
so i hold great expectations for the antenna once it is set on the tower at 42ft/
the idea of the exercise was to look for a small effecient antenna for town blocks and villages,this fits the bill and is still competitive.

>tuner to handle.

If you're feeding a half-wave dipole with 50 ohm coax, cut the dipole to 468/f to start with. For example, for 7.2 MHz, it would be 468/7.2 = 65 feet, fed in the center. This is only a starting point, however, since the exact length is affected by how close it is to the ground, trees, buildings, etc. Make it a little bit long and then using an swr meter, cut off an inch or so at a time till it's just where you want it.

You can also feed it with open wire line but you'll have a severe impedance mis-match which you'll have to correct with a tuner. The advantage of doing it this way is the length of the antenna is not critical at all and you can operate it on several bands fairly efficiently. The disadvantage is... you need a tuner. And when you have a tuner, you will be readjusting it whenever you change frequencies very much. It gets old after a while.

Generally speaking, trying to operate several bands with coax, even using a tuner, is not advised. Coax is very lossy when operated with a high swr. Most folks just use coax with a properly-trimmed dipole. Works great.

On HF, with in a few inches. It gets more critical as you raise in
frequency. UHF, is very critical.

Well, I don't see how Yaesu could shield their FT-847 any better. It has an all metal case with 7 layers of component boards inside, with each board surrounded with its own metal shielding. In addition, a large number of the components on each board has still more shielding. Yet, this radio is really bad when it comes to poor grounding.

In Washington State, where the ground was relatively dry and rocky, I had to install a ground system consisting of multiple rods to get proper performance. On the other hand, here in South Carolina, where the soil is moist and tightly packed, a single ground rod was plenty.

In my specific radio, the results of poor ground makes itself known in the sideband performance - a slightly distorted signal. However, from what I have heard, this appears to vary with each radio (others have reported other problems, all solved with a better ground). The manual warns about this, but most (like myself) ignore it until a problem crops up.

Anyway, I'm not so sure it is poor shielding, or just a result of trying to stuff so much stuff into one radio. I don't know enough about all this to judge. But, I do know I love that radio's performance, and its capabilities. So, I can deal with this minor issue.

Using a relative field strength meter in conjunction with an SWR meter
is a useful approach. Often, you can obtain the same low SWR reading
using very different settings of the inductors and capacitors in a
matching network, yet one of these will almost always yield by far the
highest field strength. It is instructive also that sometimes your tuner
acts like little more than a dummy load. On 40 and 15 I peg my FS meter,
with its sensitivity turned all the way down. On 80, with the sens.
control full CW, I can barely budge the needle no matter what I do. If I
relied only on the SWR meter, my feelings might be hurt that no one
answers my calls on 80 :)

Is it patented in the UK?

If an Amateur builds one of these for himself, or a friend, I can't see how it's possible to practically enforce the patent unless NC drives around the whole of the US looking at what's on the roof.

In fact, unless you have permission to go up onto people's roofs, enter their property, etc., you're on a hiding to nothing.

Seems NC is more worried about bad publicity, and making silly contributions like he has to various NG's frequented by Amateurs isn't going to sell the product.

If you can't stand independent critique then you shouldn't try something new.

Yes you can, but I don't think anyone would recommend it.

You are risking that new amateur equipment unnecessarily, if you do use it,
then use your lowest power for very short qso's.

Hi OM,

All that you say is true, however, it doesn't necessarily disqualify an antenna as being useless.

Occupying a small space is an asset to many, having a match is another asset. If one is educated to the cost of such assets, then the informed Ham can make an educated choice. As I pointed out elsewhere, this antenna is probably more suitable for receiving than for transmitting if one is terribly conscious of efficiency (which, actually doesn't go very far as an argument).

Now as to the matter of being able to turn it. That is a matter not of terrible concern to a designer, it being more so the implementor's problem. This disconnect may seem brutal, but it is often the case that an inventor entirely oblivious to the real needs of his customers often finds a less than bright (in the inventor's estimation of course) huckster can move these twisted resistors by the carload by including a pail of lossy dirt.

Does anyone believe that it is an easier job to fashion an 80M version than simply lay ground radials against any handy vertical radiator? No, and how many builders to the 10M version are going to tolerate the loss of planting a dwarf in their garden a half inch above the soil when a six foot elevation would offer so much more? Of course they lose the F/B at the cost being able to hear better; they also lose the convenient match afforded by the ground providing half the match.

Such a quandary. But if the user has none of these options in the first place, the original position seems to glow. Too much attention is paid for these concerns, but people are concerned none the less. Consider if you worry about a 6 dB loss getting a signal out of the antenna; then how do you feel about the 100 dB loss getting a signal out beyond 10 miles?

Hi OM,

You are welcome. Feel free to use the design if you wish, please
observe the cautionary statements and be doubly aware of the high
losses presented to maintain the characteristics. Also do not be put
off by the high sensitivity to ground (that is, sudden losses of gain,
or poor F/B with variations in the antenna's relation to ground).

Some may recall the experience of Jean Michel's implementation of the
non-fractal version and how difficult he found to bring it to match.
With the perspective of earth in mind, this could be anticipated and
"optimized(?)" again.

I asume that you want to use the tuner for receiving and that the tuner is T type, with switched coil and two variable capacitors. If the antenna is long enough, usually the tuner usually does not impove the reception much. If the antenna is short, set the antenna capacitor at maximum, and manipulate the transmitter capacitor and the coil for maximum signal strength. Ignacy, NO9E

It depends on the antenna. Most discones will work fine on 2-
meter, 440, 900 and 1.2ghz. The Radio Shack telecsoping scanner
antenna will work on 2-meter and 440.

Yes, you certainly can. The Radio Shack magnetic mount scanner antenna is even rated for transmitting. The original one was tested by someone with similar questions and turned out to show a low SWR in the Amateur 6 meter, 2 meter and 440 MHz bands. Radio Shack now sells this as a transmitting antenna good up to (I think) 25 watts. However, I don't think this is available in NZ.

If you have an outdoor scanner antenna, and a SWR meter, why not try it and see? It's unlikely you will have an SWR worse than 3:1 and if you do, stop transmitting; your question will have received a negative answer. Modern radios can take that for quite a while anyway. If it's less than 2:1, and the results on the air please you, then you have received an affirmative answer.

The thing to beware of is small mobile or indoor scanner antennas which may contain very small diameter conductors. These could burn out if you transmit into them.

Hi Dave,

This could last A VERY LONG TIME.

At least mine did until the winter storms last year broke several
trees 20 feet up. Of course one tree fell across the ascending line
and thwack! my driveline was pulled to max strain (and beyond).

I have one broken tree that still resides in the canopy, ridgepole
style (the trunk is easily 30 feet long and held in the other trees'
branches 20 feet up). Been that way for more than a year (it was
another tree that actually broke the line).

Anyway, it was a strong performer for such a simple cast.

Hi Bart,

You, too, have an optimistic bent. Have you gotten any clarification of all the good points and questions that you arose for the $1000 challenge (which appears to be moribund)? The questions above have the same sane and careful attention to the real matter, but track records being what they are....

The problem with your expectation is that you are under the presumption there is some "science" behind these choices of antennas offered for review. Bart, these examples are nothing more than discoveries obtained by wading through un-revealed candidates. This is called Hi-grading and is a sham of what is being presented as an objective approach.

If you note the "qualifications" of either the challenges or the offerings for review; they all come with the attending crowing about no other design besting it within certain constraints (the same as the antenna under consideration, often). That is, all the commendable issues you list above are found AFTER the candidates have been put through the sieve, not before. As such, this quality of research offered is found in the luck of the draw, and not through some formalistic and rigorous survey.

EZNEC is an antenna analysis program. You describe to the program what the antenna physically looks like, and it tells you the pattern, impedance, currents, and derivative information (like front/back ratio, SWR, etc.). You can get info about EZNEC, and download a free demo program (fully functional except limited in antenna complexity) from http://eznec.com.

I'll have to let someone else answer about TLA. I heartily recommend TA (terrain analysis), though. It shows the effect of terrain of arbitrary cross-section on the pattern. It uses a free-space vertical pattern from EZNEC or any of Brian Beezley's modeling programs as its input. You can get information about TA from k6sti@n2.net.

I'm uncomfortable with anyone depending on EZNEC or any of the modeling programs to give precise results when the accuracy depends critically on ground characteristics. These programs all make the assumption that the ground is perfectly flat, and homogeneous to an infinite depth. In average soil, the skin depth is about 16 feet at 3.5 MHz, so there's considerable current at over 20 feet depth. Ground is often stratified, unlike the model. Even if you knew the conductivity and dielectric constant of each stratum, I'm not entirely convinced that you can replace it with a single "equivalent" homogeneous ground and get equivalent results. And in an urban environment, there are often other buried conductors within the antenna's field. So whenever you see a design which the model shows depends critically on the ground characteristics, expect to do some tweaking at best. But you might not be able to achieve the model results at all.

Hi Roy,

What you say about the connect between modeling and reality is a
necessary warning coming at the right time.

I am confident in that the reporting of other implementors with their
difficulties described much in the same tenor as your cautionary
statements above strikes to the very heart of the matter. As to
precision, I have no illusions as to this issue.

However, if we were to remain implementation neutral, and IF there are
no program oddities that relate to presumptions made; then we have us
the basis for a decent comparison. My reliance on a perfect ground
with my fractal surveys was done principally for speed. Behind that
practical concern is the logic that if my modeled antenna suffers for
some reason, then the standard antenna suffers equally (and presumably
for the same reason). There are certainly differences that could clash
with this expectation, but I am willing to discuss them if the time
comes.

As such, until this review of the k2, I rarely consider "real" ground.
The difference with this model is in its tightly bound to ground
nature to supply all the key characteristics. Arguments made over
differences in ground are bound to lead to no conclusion at all -
ground is too variable as you point out above. Thus I am satisfied to
allow the defaults for "real" ground to sail right through (which is

to say, these defaults constitute the standard for my grounds - if and when I choose to consider it).

Think of squeezing a very small version of an antenna into *very* limited
space.

Forget about ham bands and think small.

114. Twin-ax.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-15 00:00:00 UTC
From: Terry Sanford <tsanford@roadrunner.nf.net>
Message-ID: <39998F82.75E08A65@roadrunner.nf.net>
Source record: 182636

Other day in a junk store I saw a plastic bag containing some 30 to 50
feet of twin-ax such as is/was used by IBM computer systems and several
of those connectors that at fisrt glnace look like 'N' coaxial
connectors, but have two pins.
Does this have any RF use e.g. as a 'ba;lanced' feeder to an antenna
(receiving only) and if so what would be the characteristic impedance?
In other words should I go back and offer him 5 bucks?
Comments welcomed. Thanks.
Terry S.

116. Radial lengths

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-15 00:00:00 UTC
From: Larry Benko <benko@aztek-eng.com>
Message-ID: <399997C1.903DDED5@aztek-eng.com>
Source record: 182638

I am helping a person put up a low profile antenna which will be
an inverted L (30' high & 60' total length) fed against ground
and matched with a tuner. Given that he would like to load it
on all HF bands (except for 160m) and will probably only opt for
only 6 or 8 radials, what would be the preferred radial lengths?
Initially I thought that 1 for each band of 1/4 wavelength + 5%
and then thought that a few longer ones would be better.

Thanks,
Larry, W0QE

If the radials are right on the ground or buried (even slightly), they won't exhibit any substantial resonant effects. So the longer they are, the better. You do reach the point of diminishing returns fairly quickly, though, so making them much longer than around 1/4 free-space wavelength or so won't help much unless you have a large number of radials -- but it won't hurt, either. The number really required depends on what the antenna's feedpoint resistance is on each band. You can get this information with modeling if you want. But 6 or 8 radials will probably get you within a couple of dB of a perfect ground system. Make them all as long as practical, but making them longer than about 1/4 free-space wavelength on 80 meters would largely be a waste of wire.

Been reading the mail. At least N1IR gave something to test.Got the mfj 224 up and tested the flyer to a vertical with 8 radials on 52 direct. Have a flat grassy backyard here.

From 70 ft away the flyer has a gain down by less than 1/2 to 1 db from the vertical and the backside is down 11 to 12 db. I used a 4 element beam on the rx end and my beam was up 15 feet.

Make your own conclusions. Just keep me out of the hate fest.

Source record: 182646

Are they still around? They were for so long a fixture in the
advertising pages of QST.

I have some questions about those antennas:

They were advertised as multi-band, trapless jobs. According to one of
their ads, the thing was like 23 feet long,
requred NO radials, and was fed with good ol' low-impedance COAX
cable.

Question: How could it be run as a multi-band ant with just co-ax??

The aforementioned ad stated that for 80 and 40 meters, a tap location
was found experimentally on the loading coil, to give a proper match on
those bands.

On the higher-freq. bands, the antenna system relied on an ATU _or_ the
pi-network at the output of the rf amp, to provide matching.

I don't understand how the coax could act as an efficient transmission
line, especially in the latter case (on 20/15/10).
Wouldn't it have been much more efficient if the trans. line in that
case was an open-wire parallel feeder? Wouldn't coax have been really
lousy, in comparison? Wouldn't the losses due to a (I would expect)
very high SWR on the line, be considerable? Why co-ax, then?

Considering it in another way -- on 40 and 80 meters, say the radiator
with loading coil amounted to an electrical quarter wavelength. OK.
Then it would be compatible with 50-ohm co-ax. BUT that would require a
ground/radial system -- no? How could it be an effective system, on
those bands then, _without_ any radials?

Very interested to hear what the deal was, behind this ant. Always
sounded a little too good to be true...

Anybody got the scoop on this?

thanks all

Hi Mark,

It sounds like you tested the antenna on two meters. Is that correct?

How high above the dirt was it?

How high was the vertical?

Thanks, Tom

128. Re: PCR-100

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-15 00:00:00 UTC
From: mthompson14@yahoo.com

Hello,

I just recently purchased an Icom PCR-100. Couldn;t wait to
get it home and hook it up. Keep in mind I'm new to Radio so take my
comments for what they are worth.

I'm pretty pleased with its performance. This is a good radio
for the beginner. One thing I don;t like about this radio is that it
only has FM WFM and AM, there is no SSB or CW reception, and becasue
of this I'm missing out on alot.

The documentation only garuntees this radio to receive as low
as 500KHz. I have successfully tuned mine down to about 30KHz. Loran
at 100KHZ being predominatly strong.

If you don;t mind dropping the extra money I would suggest
buying the PCR-1000 this has the added benifit of CW and SSB
reception. Also if you purchase outside the US you can get these
radios unblocked meaning you can receiver cellular phones, if thats
your thing.

Another thing you might want to take into consideration is,
that I have heard rumors that this receiver gets alot of noise coming
from the serial port of the PC it is hooked up to. I myself have not
noticed anything but then again I'm no elmer:P

Hope this helps
Mike T.

I have a Butternut HF6V which I'm very well pleased with! I did a lot of research before buying and all indicators say the Butternut is the best vertical on the market. Of course, I would like a beam with a rotor but can't have it in my neighborhood. Follow the instructions for tuning and you won't need a tuner except for maybe the lower bands. I have my ground mounted with about 8 radials of diferent lengths in a pie shape around the base. All in all, if you want or need a vertical, get the Butternut.

Appreciate this info, Roy.

I guess what this boils down to, and I should have posted it this way in the first place, is What would be the best and easiest way to model the dipole we've been discussing in the other thread (Homebrew Dipole)?

Which program is more "user friendly" and will show me a radiation pattern based on a vertical dipole

Thx, and 73.

Source record: 182654

My HF6V has been operating for about 7 years now and I'm very happy with it's performance. Over the years I've compared Cushcraft, and GAP antennas, and ended up keeping the Butternut.

Mine is ground mounted with about 32 buried radial wires (laid out in a spoke fashion) and works like a charm for DX.

Best bang for the buck antenna on the market - but - I won't sit here and say there is a tremendous amount of difference between it and a wire antenna, if you have room to put on up. That debate has been going on for a long long time. Various comparisons (I like fiddling with antennas) between my HF6V and a G5RV (102') and a 125' long wire had the vertical and wire antennas running neck and neck in most instances. And putting up a dipole or G5RV is a heck of a lot cheaper than any commercial vertical.

For an excellent vertical go with the Butternut, but first, play around with some wire...

Source record: 182656

I am plunging into intricacies of antenna modeling using EZNEC.
Have some questions:

1. I see that metric formula for wavelength is not 300/f as we used to use.
What is the reason for 298 something, air dielectric? More precise speed of
light/RF?

2. When modeling quad loops, what are the recommended segment length in the
vicinity of the corners? I understand that programs are having problems with
sharp wire corners. Say recommendation for 15m loop.

3. Resultant pattern plots, are they containing both polarizations, or is there
way to see each polarization separately?

4. With windows version, is it possible in the near fututre to see results of
wire manipulation by mouse on the SWR and pattern plots? It would be really
neat for optimization exercises.

If you check the SWR and probably keep the power under 50 watts or so the antennas should not harm the rigs at all. Some antennas will not handle very much power. Over the last 25 or so years as a ham I have used just about anything that was handy IF the SWR was under 2:1 over the band.

They may or may not give the performance of an antenna designed for the ham bands. Doing a compairison one day with a friend and changed several antennas on his car and checked several repeaters. It depended on where the repeater was in relationship to the car as to which one gave the best signal. On a whime we checked the 40 meter whip on his car and found it had a low swr on 2 meters. It even gave a beter signal from several repeaters than a 5/8 wave whip.

Wow! Thanks! Although I'd never have guessed that concrete
has better conductivity than dirt. Although, given the
concomitant moisture, it's quite credible. I could get
into a lively discussion about the "Lightning is RF"
part, in that I'd say it's more like a spike, which has
harmonics all the way up the spectrum, but I don't want
to start a debate until I digest this new information.

Thanks!
Rich

Let me answer for Roy, from outside the "provider" side of the house- I think EZNEC (Roy's own program) in its current, Windows, version is so user friendly it is like shaving your own face.

It is easy- and fast, and lets you cut and try until you are happy with the results.

My only problem with it is that I'm not enough of an antenna expert to really wring it out.

It's good.

Gerald- Unfortunately, until the patent is posted, we have absolutely NO idea what it covers- it could be the K2, the FQY, or a replacement for damaged butterfly feelers. Considering the timing (LONG gestation period for Patents) I doubt it is the K2 Flyer. In addition, the K2 is such a pitiful excuse for an antenna, I doubt even Chip would put out all those $$$ to patent it.

(Just guessing)

EZNEC is a Windows program which allows you to analyze antenna
performance under various conditions, and allows you to modify the
antenna itself to see the effect of the changes. Download a demo copy

143. Slinky Antenna construction question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-15 00:00:00 UTC
From: Dan Yemiola <dyemiola@LexComInc.net>
Message-ID: <399A1607.5BE80D81@LexComInc.net>
Source record: 182665

I have to put my HF antenna in my attic under the roof. I have 32 feet
of free space.
I am thinking of using slinkies. I would like to get the antenna
resonant at 80m.

Questions:

1) Has any one built a 80m dipole from slinkies?

2) Or would an end fed wire be better?

3) How to feed Them?

4) Would end fed slinky allow the antenna to resonate on more than
band?

5) Does anybody have any experience they would be willing to share?

Joel,
The 'Gotham' verticals were one of the worst antennas ever
'thought'
of by man! Remember that you ~can~ make any length antenna work on
any
frequency, if you want to 'bad' enough. Probably won't work well, but
it ~can~ be done.
I think there was a total of 2 people who ever got a 'Gotham' to
work close to what you'd call 'well'. Neither followed the direction,
both did use a good ground system, and neither kept the antenna for
long.
(I'm sure you can guess that the above is 'tongue in cheek'.)
And, your correct about the 'too good to be true'... it was.
'Doc

Bill:

Thanks for the input on this one, too... Another big question, though....

How could I test field strength without a field strength meter? I don't have access to one that's worth a darn. I suppose I could get one of the cheapies from RatShack, but I'd really like to do this right... Is there a way to test field strength without said meter?

I know its a strech, but, well, I'm of limited means, which is one of the reasons I'm building my own antenna, rather than buying one.

Thx, and 73

Why not just staple a dipole to the peak of the roof, or go with an inverted "V" down one side of the slope of the roof? Using the aforementioned electric fence wire, it should be near invisible up there, and drilling a hole in one of the sewer drain breathers, you could pass your feedline thru that to the roof, making it almost undetectable as well. Of course, you'd have to wetherseal it back up once the feedline was in place, but it should work. Of course, I don't know the details of the design of the antennas, but I've heard of people doing this, and having it work nicely.

HTH.

I have a similar problem with a computer monitor, at least until it goes
into powersave mode, resonant at 27.385 or thereabouts. I simply set
Windows to turn off the monitor quicker, and blammo, problem solved...

It might have something to do with the flyback?

I think Ed had an excellent point: tell him what you think is better for DX at this height.

The K2 doesn't not "hear worse" than a dipole; is close or equivalent to a 1/4 wave monopole; and beats a 1/.8 wave for DX.

Why do you guys want to deliberately mislead people?

What's wrong with you Dave?

Whatever the performance of fractally loaded antennas, I think they are possibly mis-named. The Mandelbrot set seals in permutations of integers, where the fractall antennas I have seen deal in fractions. Perhaps they should be called fractional antennas.

I respect your opinion but I, and others, are using the conventional
definitions. The K2 Fractal Flyer

(see http://www.fractenna.com/ham/hampage6.html)

Is an excellent case in point. Both fractals used are simple and well-known.

Run the wire from the "unreachable area" to the side of your building at an upper floor, then down to your apartment window and through. This will work great, provided you can gain access tot he roof or uppe rfloor.

169. Answer to Ed's question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-15 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000815074414.11447.00000207@ng-mf1.aol.com>
Source record: 182750

Amidst all the dross from the alleged 'deafness' of the K2 Flyer, we have a post from a newcomer asking 'what's better'?

Why do we not have an answer for this?

Could it be that, for those who must deal with low heights, a directional antenna with equivalent, or nearly equivalent field strength at low (DX) angles to a 1/4 wave monopole--virtually twice as high--is NOT advantageous?

Or are those who want to hoodwink fellow hams that a new technology is a useless one-- do they want to keep other IGNORANT?

Go try it yourself, over real ground:

Model an /18 wave monopole, with, say, 8-10 radials;
Model a low dipole up 1/8 wave;
Model a sloping dipole up 1/8 wave;
Model a horizontal loop up 1/8 wave;
Model a mobile whip with radials;
Model any other antenna in a small footprint and low height.

Model these over poor to good ground and look at the field strength at low angles, say 5-15 degrees.

Then decide what's a "dummy load" and what's "deaf".

The K2 Fractal Flyer was designed because people ASKED for it. They wanted a low height antenna, with no pretensions that it would work like a Yagi up 100 feet--BUT they wanted something that would be directional and work DX well.

So, go ahead: give us that ideal solution for an antenna restricted to 1/8 wave height. Then tell how the K2 Fractal Flyer compares.

On the day of issuance of my first antenna patent, I want to pay a special tribute to Chuck, K1KW.

Chuck used to be WA1EKV. As a SWL, at summer camp in 1966, I spent hours listening to Chuck on the Hallicrafters (later Hammurlund) receiver, along with other stations. Occasionally I would even hear DX, such as Siberia. But every day, during science session, I would fire up the golden tubes of the Hallicrafters and almost always found Chcuk on, saying something interesting. That Fall I got my ticket and became WN1HBX.

Wow! I was hooked.

Anyway, Chuck knows how his on the air activities contrributed to my inchoate interest in radio and telecom, and this seemed a good time just to publicly thank him for the inspiration. Where that path has taken me has not always been sure or successful, but it certainly has been fun, exciting, and educational.

So, thanks Chuck! I hope you remain an inspiration to me and others for many years!

Wound about 200 yards of wirewrap wire on my homebru version flingshot's reel. Seemed about the same weight as the 10-lb nylon line it replaced.

2-oz weight used; first try, put about 100 yds of wire atop a line of trees. Put another hundred in the opposite direction. Now have a 200-yd dipole facing N/S. Wonder how long it'll last in the .-- -..- ..--..

It certainly can't be seen easily, even though I used bright orange wire!

You might try coupling a low-wattage light bulb to your antenna, and
then tune for maximum brightness. When I was a kid, I used to tune up
my transmitter by just connecting a light bulb across the antenna
terminals.

"Ed",

I did a search of Dejanews. Thank's Rick for pointing that out!

It's interesting that you have never posted anything to any newsgroup
or public forum ever before in your "life" and suddenly appear here to
defend Chip from an AOL account.

Nice try Chip, but you've worn that ruse out.

Bart, WB6HQK wrote:

"The trick is that the stub is perpendicular to the primary radiating elements and is resonant for the common mode."

That makes the series current path through the 1/4-wave stub 1/2-wave long. This stub then produces 180 degrees of delay to add to the 180 degrees of delay in a 1/2-wave dipole. 360-degree phase rotation puts the starts of current in the antenna elements in phase.

A quarter-wave stub and a 1/2-wave antenna element in series produce the same phase rotation as two 1/2-wave antenna elements. The difference is that the stub does not radiate.

The stub wires are folded into a parallel transmission line configuration. The distance between the wires is a small portion of a wavelength. So, since the current is balanced in the wires, a distant point will receive balanced opposing signals, or in other words, the 1/4-wave stub does not radiate.

So, we can have a 1/2-wave dipole connected at its extreme ends to additional 1/2-wave elements through 1/4-wave stubs to produce (3) 1/2-wave elements in the same alignment, and with the current flowing in the same direction in all elements.

Best regards, Richard Harrison, KB5WZI

Tim,
I don't have any comparative results but can state that the 6M antenna is easy to assemble, is well designed, and works well.I talked to another ham on Saturday who also has one and he said he had just worked many stations in the midwest, Canada and Mexico from here in Northern California.

The SWR is good across the band.

If you are interested in a 2M LP, I make LPs for 2M, 220 and 440 bands
The 2m and 220 are 5 El, 24 inch boom, where the 440 is 7 el, 21 1/2 inch boom. If you are interested, e-mail a reply and I'll send directivity plots, SWR
and more.

Best wishes de ray, w6fya

> useless one-- do they want to keep other IGNORANT?

What new technology? It sounds like you are claiming the K2 Fractal
Flyer, whatever that is, outperforms more conventional antenna systems
meeting the same constraints.

If you really want to challenge the rraa community, you might want to
state both the objective function (Figure of Merit) and the
constraints. The definitions should be formal enough so that anyone
skilled in the art can objectively and unambiguously apply the
definitions to any candidate antenna system.

> Go try it yourself, over real ground:
>
> Model an /18 wave monopole, with, say, 8-10 radials;
> Model a low dipole up 1/8 wave;
> Model a sloping dipole up 1/8 wave;
> Model a horizontal loop up 1/8 wave;
> Model a mobile whip with radials;
> Model any other antenna in a small footprint and low height.

Looks like the primary constraint is that the antenna will be sited over
a 'real ground' and must be fully enclosed in a box 1/8 wl high X 1/2 wl
long X 1/4 wl deep.

Am I correct?

Good engineering practice would be to softly constrain the system to be
'easy' to construct and maintain; structural simplicity and
straightforward tuneup is a necessity for many radio amateurs. I assume
the system should maintain the desirable (objective) properties over

typical environmental variations such as rain, ice, wind and snow.

> Model these over poor to good ground and look at the field strength at low
> angles, say 5-15 degrees.

I take it that the objective is to generate as much radiation at takeoff angles in the range 5 to 15 degrees. To what extent, if any, is directivity desirable?

Richard, I had no idea that you were old enough to recall the famous trademarked concept behind Charles Atlas' famous body building course of the late 30's. He somehow stumbled upon what is know termed the isometric concept of exercise and branded it Dynamic Tension.

I also suspect that, clever silver-tongued devil that you are, you deliberately planted this little phrase in order to see who was reading carefully (!).

Hi Larry,

There is no doubt the design may be improved, but at what cost?

This is something I try to point out at my page
http://www.qsl.net/~kb7qhc/antenna/fractal/n1ir/k2/index.htm
wherein I caution the constructor not to use "improved ground."

All improvements will eventually lead away from the desired (?) front
to back performance as well as the wide match. Thus, for this design,
the issue of improvement is a loaded pistol pointed at the head. Do
you really want to improve the trigger sensitivity?

On the other hand, QRP operators seem the least likely to use this
design for every reason you list above. But back to improvement (and
damned the cost!).

First, what about the design is appealing that you would want to keep
it - and optimize it? What about the design is appealing that would
remain so if optimized? This last is a tough question, because it is
like choosing the fastest horse and then hobbling it for training and
putting a 300# jockey on its back for the triple crown. Still a nice
horse, but no longer a runner in the race.

I would like to point out that all information revealed about the
original design is accurate, all the information revealed about the

replica is also accurate (or as accurate as that found for the original). The difference is there is more information to be had about the original design that gives a fuller picture of its inadequacies that have been downplayed or omitted altogether. That "more" information is found at my page (and I'm sure there is even "more" than that).

This antenna is very tightly bound to ground to give its claimed specification. This is not what I would call a suitable QRP characteristic, but then there is a market for air-cooled resistors (directional or otherwise). True, a considerable amount of signal is pumped right into the ground (by design); but then it does achieve a decent match and a decent F/B for that penalty. However, it would probably serve better as a receiving antenna in that regard (where gain is cheap and doesn't take Watts to achieve). This is probably cold comfort tho' because the user would then need a radiating source and hence another antenna. I doubt a two antenna solution is a useful solution for QRP.

Stick with first principles. Build a good ground system if your preference is vertical, and then look at the variety of designs at my page:
http://www.qsl.net/~kb7qhc/
The extent of data may make selection difficult, but you will at least have a survey of a wide variety of fractal designs, plus discussion that also allows you to scale to your own form (if you think you've got the killer fractal that has yet to be put into wire form). Let me point out that even with a killer fractal, you are extremely unlikely to hear the difference over a simple well implemented vertical it is supposed to replace.

The best you can expect is from a quarter wave physical sized fractal of high dimension. The worst you can expect is to have to erect it (what can I say but sorry?). If you are a real glutton for punishment, then build a very big fractal and enjoy wide open matching over considerable tuning ranges. Be forewarned that the extremely wild turns and twists lead to some very non-intuitive lobes developed. They may have lotsa gain, but that gain may be in the direction of alpha centauri.

I hope this doesn't scare you away, the only suits that will be won over fractals are the suits to recover for the abuse of one's sanity. If you make any attempt to erect one of these, then you have already lost your case in that you have failed to demonstrate you had any sanity in the first place. This is from one who knows, a fractal fool.

Hi--

A 30M version of the K2 Fractal Flyer would do nicely.

Measurements of the design confirm its near unity gain with a 1/4 wave monopole at low angles (* this is an actual range measurement*), and modeling reveals that it has over 2 dB gain over a low dipole at low (DX) angles. In addition, it is superior to the low dipole in cutting down interference from local stations from skywave, as it has lower gain at high angles compared to the dipole.

You can see the K2 Fractal Flyer on:

http://www.fractenna.com/ham/hampage6.html

In rec.radio.cb WildBill <wildbill @hose.com> wrote:
: sideband a swr meter is how you measure if it is 50 ohms or not ... 50 ohms
: would be a 1:1.1 swr , 100 ohms would be a 2:1 swr as well as 25 ohms would
: be a 2:1 swr ... trim each end the same or add the same to each side to
: get your swr down to which every frequency is of your interest..

I have to disagree with this generalization. It is fine for any antenna that is close to 50 ohms impedance at resonance - but not a lot of help otherwise.

For example, some antennas are actually close to 30 ohms at resonance. You will radiate more power if the antenna is tuned for a SWR of close to 2:1, NOT 1:1. The problem is figuring out if that impedance is around 30 ohms or around 100 ohms - using just a SWR meter.

That is why it is recommended that the SWR meter is only used to make sure the impedance is within the range that the transmitter can handle. Tuning the antenna is done by field strength measurements - just tune for maximum radiated signal, and let the SWR become whatever it becomes. If it is out of the range that the transmitter can handle, then the antenna design needs modified in some way - then retune using the field strength meter.

That's quite a design Richard, You did a cool job on it. Congrats on the new antenna.

I ran the numbers and found that the thing is pretty lacking in gain at low angles but the problem is so is everything else. A low height dipole is poor and a vertical isn't much better. N1IR got on here and said that this ugly wire thing beats a dipole. That has a ring of truth to it.

When I got to the fractanna sight I was actually pretty impressed with the data and presentation. Pretty clear why some people would need the antenna from that.

So my question is that if you think this thing is a dummy load what works better ? If someone can only out something small up and low in height what's going to work better for them? I think you have to give something better that fits in the space.

What's you got?

Anyone? Numbers please.

Ed

Richard,

What am I missing? This is an antenna with negative gain
that hears worse in one direction than another, is the devil
to build (by comparison to others), is extremely sensistive
to the environment, and is difficult, if not impossible, to rotate.

Did I get that right? If so, what am I missing? Why would
anyone want such an antenna? Is it just the fact that it
occupies a small space? I've been trying to figure out what
benfits, if any, can be realized with a fractal design. Chip
has been completely useless in helping me in this - I hope
you can. Thanks!

Wrong, as has been repeatedly pointed out to your.

First, you do not have a patent, so you do not have patent protection. Until you get that patent, anyone can use the information you supply to manufacture and sell devices based on your design.

If the antenna is built using information that is based on other patents in existance, then you would have to prove that your patent variation is not derivitive.

By publishing at least a variation of your design, you have just thrown away most of the enforceability of any patent you may receive. Such "trade secrets" are not called that just to be using large words. If intellectual property is willing divulged by someone having the right to do so, then it no longer is intellectual property.

Not true at all. The patent itself discloses the design. In the USA,
one may publically disclose (or offer for sale) one's invention prior
to patent award without loss of patent protection provided that such
disclosure occurs not more than 1 year prior to the filing date of the
patent application. As far as I can see, Skip has not lost any IPR
because of anything he's posted here. But I don't know his filing
date nor have I researched his posting history.

Klein, WT6G

Rich Grise wrote:
"I could get into a lively discussion about the "Lightning is RF" part, in that I`d say it`s more like a spike, which has harmonics all the way up the spectrum,---."

Lightning is a large visible electrical discharge in the heavens. Stored atmospheric potentials become large enough to break down the air`s insulating ability and the discharge starts.

No RF is stored in the atmosphere. Latent electrical charges inhabit the atmosphere. It is the abrupt start, stop, and random motion of charge flow that contain elements of radio frequency.

The mass migration of atmospheric charge called lightning contains much energy which is not classified as RF. "Lightning is RF" is a poor definition.

The antenna they call a G5RV is simply a dipole antenna, 102' feet long, with about 32' of ladder line feed in. Some people attach the ladder line to coax and bring that into the shack, some just feed the ladder line into the shack - I've tried both and settled for just using the ladder line to my tuner...works like a champ.

With a tuner (it need not be an expensive one - check MFJ) you can run all ham bands with this antenna and it's very cheap to build. Don't buy a commercial version - try building your own - it's a lot of fun and you'll learn a few things that simply writing a check wont teach you. :))

Hope this helps...

> the starts of current in the antenna elements in phase.

Are you saying the current entering one terminal of the stub is phase shifted compared to the current in the other terminal, by an amount equal to the electrical length of the stub?

Kirchoffs law states that for any two terminal device, the current entering one terminal must be equal to the current leaving the other. They must be identical at every point in time or the device is not a so called 'two terminal device'.

If the two currents are always identical, how can any phase shift be introduced by a two terminal device?

I'm a little confused about something. I thought I had heard stories
about grounding arrangements for towers that could result in the
concrete in the footing "exploding" when the tower is hit by
lightning. What would cause this if concrete and rebar is a good
ground? What should you do (and not do) in construction of the
footing to avoid this kind of catastropic distruction of the footing?
Or am I just totally confused?

Hi Mark!

Thanks for the follow up. If you wish you can post the data on the hampage6 site, or elsewhere.

I've been swamped by e-mails. About 1/3 are really puzzled by the negative gain values(the web site gives the NEC pattern at 10 degrees as about -4 dBi). It is truly unfortunate that a few mischievous hams mislead others into thinking a low dipole, or vertical, has positive gains at low angles in real situations. Also very unfortunate how one has misled with claims of 15 ohms of ground losses--when such losses cannot be determined by NEC in the way it was used.

I suppose we will next see some claim that the 2M MEASUREMENTS are not in any way applicable--even as a guide--to 20M.

Sigh.

Let me know when you have the 30M K2 up.

There certainly can not be any phase shift unless a shunting path is
involved!

The load of the second section can fulfill that function, but that
still limits phase shift to 90 degrees maximum if the device between
the sections is a two terminal device.

Anyone who has ever built and measured an antenna with lumped
components in a "phasing section" would find that out. All you really
have is a series resistance with zero phase shift at resonance, and
very little phase shift off the resonant frequency.

Klein, WT6G wrote:
"What would cause this (exploding) if concrete and rebar is such a good ground?"

Too much current in a part of a tower footing which is not such a good ground causes the explosion. Resistance produces heat. Concrete contains moisture (it never completely dries). Hot moisture generates superheated steam which explodes the concrete much as tree trunks which you may have seen exploded by lightning.

This is prevented by bypassing the strike around the tower footing with an even higher conductivity path. Heavy copper condutors and multiple ground rods are used.

Best regards, Richard Harrison, KB5WZI

Does anybody know of a manufacture who makes a line of UHF style connectors using a web structure, i.e. the dielectric is mostly air, to hold the center conductor in place? I have seen this design used for mobile antenna mounts for UHF antennas, and for coax connections used on V/UHF SWR - Watt Meters. I don't know if these connectors are custom designs or are available as stock items.

No need to complicate with energy storage, instant versus effective,
etc.. Two examples most will instantly recognize: pure L and pure C.
Either has orly two terminals and produces 90 degrees of phase shift
between current and voltage.

Best regards, Richard Harrison, KB5WZI

As luck would have it, I am in possession of a PRD angle of reflection coefficient bridge. That's all it does, give the angle of the reflection coefficient. But as you point out, this is necessary information for creating a match.

It's a neat looking gadget, and serves very well to estimate a job applicant's ability to think beyond the box when given an RF problem.

Cheers,

Cortland

No, I have not. But if you are worried about loss or an impeadance hump, just use "N" connectors. They are not that expensive and may be cheaper the this "custom" type of UHF connector.

Thanks for the response. So are you saying that you would NOT tie together the rebar in the footing? I.e., try not to make it such a good ground relative to the ground rods, etc?

Why don't the Ufer grounding systems explode when struck?

I'm confused

The device called a Constant Current Antenna uses series capacitors to resonate wire sections. That resonance can only occur if the phase shift due to inductance in the wire is equalled by an opposite phase shift in the series capacitors. The capacitors are not three terminal devices. What does the model look like that requires a three terminal device for this resonance?

Hi OM,

I am heartened by your desire to investigate these antennas. However, David's point about this being a labor of love is not to be overlooked. In such pursuits are the hazard of being disappointed.

I think there was some effort of recovery put forward in claims that there are a lot of terrible antennas that make the k2 looked good in comparison. Of this there is no doubt. And on the flip side there are a lot of lousy fractals that make this list of contenders look like winners. Picking your villains to make your hero look good reveals a basic weakness.

I have no interest in any particular design, I approach them all with neutral expectations and await for them to reveal where they fit in the scheme of things. The most interesting of traits to emerge (for my interest that is) were the designs I call wide-band at my pages. These are very high Z antennas at 377 Ohms (nice to pick something that also corresponds to the Z of free space) and they are VERY BIG constructions when wavelength is taken into account.

It is too bad that they are both big and complex. The complexity (the undiscussed cost) is something I cannot come to terms with when others ask for an example to start with. I have so much data at my pages that I pose that vast assemblage as an example of the tyranny of choice.

You may note through all the postings that no one suggests that they would build the k2 for 80M, or 40M, and the 20M example is just that, an example with all effort being put into 2M models. This is tacit admission that the k2 is not ready for HF.

You may also note the slippery slope of comparisons being made (already noted by one of our new wags). The k2 occupies a 3 dimensional space fully, and yet the counter examples are all restricted to smaller volumes. This is another reason why I only compare my

designs against two variations. The first is for my designs that "consumes" the same amount of wire as the standard monopole they are compared against. The second variation is for my designs that stand as tall as the standard monopole (and thus consuming more wire than the standard). On the one hand, I do replicate the duality of comparison (comparing large volume designs to the restricted volume of the monopole), and on the other hand I also consider the comparison of large volume designs to large volume designs.

As for complexity, let's review the k2 once again at the 80M scale. Can you imagine the problems of supporting all these angled members with a network (cobweb if you will) of ropes from many supports all trying to maintain the geometry? This is probably the biggest joke of fractals. The claim that they are small belies the necessity of ancillary structures that lend nothing to the electrical properties.

Let's face it, to support the k2 requires at least three vertical structures when we get into the scales of HF (stiff wire holding the shape of the fractal even at 20M is not a reality). This is why all such examples of "superb" designs are rarely implemented below 28 MHz. Note I said three vertical structures but what is holding that fourth lowest point off the ground? I doubt that stiff wire would suffice and we have yet another vertical element being added just to support this end of the "monopole."

This sounds like a stiff price to pay when the same structures are denied to alternative designs (the slippery slope of comparison again). But if you are going to step into the work of constructing a fractal, you are going to have to come to terms with the practical requirements (and is one reason why I unashamedly ignore them and dwell only on the theoretical).

In my mind, the simplest design would be along the lines of an inverted fractal V. One mast or support with a spray of insulated guys is used to hold the various bends and turns in place. This is not very elegant, but I think this would be a good introduction.

Also, I wouldn't worry about exact geometries or wire lengths. My replication of the k2 goes to show that even sloppy attempts to duplicate can lead to improved traits (although this was fortuitous and is not offered as a guarantee). I even added the transmission line to the model (it is in the vertical plane of a vertical polarized antenna after-all) and improved the traits even further.

Given that slop can so easily improve this wonderful new design, it is no surprise that the $1000 challenge died on its feet at such a tender young age. Then again, Bart's simple questions may have hastened that death long before the k2 appeared.

It sounds to me like two different things are being compared here. The currents at the two terminals of a capacitor are in phase. The currents at the two terminals of an inductor are in phase. Neither will produce a phase shift in the current from input to output. No two-terminal device (of zero length) can -- it violates Kirchoff's law.

>(ka5s@saber.net)

The reason why that works is simple.

The antenna has a field that couples to space and to other parts of
the circuit.

Phase shift is limited to a maximum of 90 degrees lead or lag when a
two terminal device, even with multiple components inside that device,
is connected in a system like this.

If the antenna had no common mode impedance, phase shift would not be
possible through the two terminal component or circuit.

If the two terminal device is resonant, it can have no phase shift at
all. Maximum phase shift occurs when the two terminal device drives a
zero impedance load, and the series reactance is infinite. In that
case, shift is 90 degrees. In other cases shift is less than 90
degrees, unless there are multiple components and there is a third
terminal.

A stub can have a third terminal from its somewhat low common mode
impedance (if the stub is arranged correctly), a simple L/C circuit
can not (at least not much because the common mode impedance is
extremely high).

EZNEC uses 299792500 m/sec as the speed of light. This is correct to seven decimal digits, according to the _Handbook of Chemistry and Physics_. 300 million is just fine, but the more precise value is no problem for the program.

> 2. When modeling quad loops, what are the recommended segment length in the

Six segments per side is plenty, and you can get good results with even fewer. There's no special requirement for short segments near the corners. This was a problem with MININEC-based programs, but NEC-2, which EZNEC uses, doesn't have this problem.

> 3. Resultant pattern plots, are they containing both polarizations, or is there

You can have the program show you H, V, and total separately, or just total. In the Control Center, open the Plot menu and choose 2D Fields to Plot.

Do you mean, could you move a wire with the mouse, and immediately see the SWR or pattern plot change? No, not in the near future.

I would like to hope that we can get bipartisan support for this bill,
and also for a bill exempting hams from restrictive covenants and
homeowner's associations.

I also think we should keep political discussion off of this
newsgroups, to prevent needless flame wars, insults, and hurt feelings.

Granted it's only the abstract, but how could someone get a patent for
tuning an antenna by cutting it's length? Is this a novel concept?

Slick Willy "The dirty draft dodger" takes credit for the good economy. He thinks the democrats are responsible for it. They controlled Congress for 40 years and the economy floundered, then the Republicans took control of congress and everything skyrocketed. The democrats just won't give what started under Reagan, continued building during Bush's term, and really took off when the Republican's took control of congress any credit, - and Slick Willy takes credit for it. The democrats say the budget deficit quadrupled under Reagan and I say it costs a lot of money to win the Cold war. It didn't come cheap. It was well worth the money it costs.
We Americans have no choice but to vote for a Republican President. No democrat can put up a valid argument against voting for Bush!

248. Re: Homebrew dipole (somewhat of a long post)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-16 00:00:00 UTC
From: ehsjr@bellatlantic.net
Message-ID: <399B0423.8338BBEC@bellatlantic.net>
Source record: 182456
Cross-posted to: rec.radio.cb,rec.radio.amateur.antenna

No, you are not being bothersome. But you
got a lot of answers including some bad
information which could lead you astray.

If all you want is to put up a simple antenna
that works, and are not into designing the
the very best antenna you can, then build
a dipole. Determine the length of the elements
(2 pieces of wire) by the formula :
495/frequency where frequency is the frequency
you want the antenna to work best on and is
expressed in mhz (megahertz), and the result
of the computation is feet. For example, at
28 mhz, the result would be about 16.6 feet.
Divide that by two to get the element lengths.
You would need two elements 8.3 feet long. That
will give you a good starting point somewhere
near 50 ohms impedance at 28 mhz. You can then use
an swr meter and adjust the element lengths
for the best match as indicated by the meter.
You must shorten (or lengthen) an equal amount from each
leg of the dipole. You make your swr measurement
with the antenna installed, then lower it, shorten say
1/2 inch from each end. You raise the antenna back
to its proper height and measure the swr again. You
repeat the process of lowereing, shortening, raising and
measuring until you are satisfied that you've got a low
enough swr. If you find that shortening the elements
raises the swr, then lengthen them instead.

The exact impedance of your dipole will depend
on surrounding conditions, how close it is to
the ground and so forth, so the use of the formula
is only to get you in the ballpark.

Now, the rest of my answer will be in response
to your post, and will be somewhat harsh.

sideband wrote:

> Uh, whoa... inductor? Grid? Huh?

> two wire halves of a verticle dipole, cut those wires, attach them to a block of
> some sort, feed the coax, throw it up in the air, check the SWR's, tune it and

> go....
>

You already know that stuff. You posted it in your first post.
Your first post indicates you are looking for an optimum
design, not the soft bullshit you posted above. If you
want to optimize you gotta learn. You also indicated
you are envisioning running a 200 watt amplifier. "Serious
overbuilding" you called it.

> Now I need to build a gamma match or something similar to get this thing to work?
> I had always heard that the beauty of a Dipole was its simplicity...

If you want advice, then spend some time reading it properly.

> So now I need to ask a bunch of questions, because (and yes, I'll come right out
> and say it) I'm ignorant where these things are concerned..

No problem when you don't know, and no problem when
you ask

> I'm a person of meager means. I can only work 4 hours a day (not by choice), so
> this dipole project, which will probably exhaust me when I put it up in the air,
> was conceived to both save me a few dollars, let me talk on the CB farther than
> the four miles I get out now, and get me some limited exercise.

Build the 1/2 wave dipole you mentioned in your first post, and that I
outlined above and that has been explained in other posts. Undertsand
that we cannot optomize it for you to exact dimensions, which will
depend in part on the environment where it is installed.

> 1. How do I measure the resistance, inductance, and/or reactance at the feed
> point of a dipole? I have access to a relatively decent DVOM (if Fluke is
> decent), an SWR meter, and that's it...

You don't. But my post was prompted in response to a post
that told you that you measured impedance with an swr meter.
I corrected that so that you would not be mislead.

>
> 2. Will I need a degree in Electrical Engineering to, once I've figured the above
> out, design and build this matching bridge/gate/whatever? I'm pretty handy with a

> added my own little twist to the clarifier mod in the GrantXL/148/2000 that works
> VERY well), but I've never done anything such as this before, dealing with things
> I cannot directly measure. New ground for me.

If you build a 1/2 wave dipole as described and feed it with 50
ohm coax, you will not need a matching network. You will
adjust the length of the elements for the best match.

>
> 3. Would it be simpler to design an antenna that had 50 ohms resistance in the
> first place, without the reactance/inductance, or would it be simpler just to

> make up the difference once an "efficient" design was created?

Yes/no/maybe - depends on what it is you have in mind. If all you
want is simple, go with the dipole. If you want distance and all
other factors are secondary, go with a beam, or a quad, or whatever -
but you have to be able to choose between the tradeoffs. That's
what engineering is all about - creating the best design for a given
set of circumstances.

> I know, I'm being bothersome, and for that, I do apologise. I'm just trying to
> understand and learn new things.

Again, it's not bothersome. But expect to do some work in
reading and trying to understand the answers. And understand
that you set a real bad tone from the outset with your mention
of the 200 watts for a CB antenna. Hams love to help others,
as a general rule, but not to help in illegal activity. 200 watts
on CB is illegal, and, frankly, pisses a lot of us off. You
already received some replies where that is evident.

200 watts is legal on the ham bands, and we regularly
talk all over the world. There is no legal restriction
on you becoming a ham in the USA (I'm assuming
that's where you live). Yes - you have to work for
the license. That's one of those "engineering" choices:
am I content with CB and its limited range, power
limit and bandwidth, or am I willing to work for
the latitude that ham radio would allow?

Nothing wrong with being content with CB.
But your expectation of posting a question
here, which happens to reference the
inclusion of possible illegal activity, and receiving
a single, well informed and crystal clear set
of instructions to enable you to do what you
want is unrealistic. Those of us who have answered
have, for the most part, tried to be helpful. In
return, do us, and yourself, the courtesy of reading
what was said carefully.

Klein, WT6G wrote:
"Why don`t the Ufer grounding systems explode when struck?"

Ufer grounding systems are susceptible to exploding if in harms way and exposed to the extent that a tower base is to lightning, but does have an advantage. A reinforced concrete slab is usually a larger surface in contact with the soil and thus has a lower current density. The Ufer can be a good r-f ground, and a good safety ground.

There are safety grounds which prevent shock at power frequencies. There are r-f grounds to complete radio circuits. There are grounds to complete the lightning discharge path. Only the lightning ground must handle enormous currents.

Would I tie together footing rebar? You betcha. I always have, and I`ve supervised contless tower constructions. It would be fruitless to try to insulate rebars and extravagant to insulate towers from their bases if they did not require base insulators to function.

No need for confusion. Ufers are good safety grounds and can be good r-f grounds. They sure can avoid static electrical build up in a grain elevator or powder magazine. You may connect your a-c, r-f, and other grounds to the slab reinforcing bars in your house, but regulations require you to also have a connection to a continuous metallic water supply system or ground rod(s). Regulations require you to interconnect all grounds including tower grounds, and to keep the tower bases from exploding, it`s a good idea to have each tower leg attached by a low impedance connection to its own ground rod.

Best regarfs, Richard Harrison, KB5WZI

> ground? What should you do (and not do) in construction of the
> footing to avoid this kind of catastropic distruction of the footing?
> Or am I just totally confused?

A good ground in this sense is not necessarily a right ground, but
just a low resistance ground. However, current flowing through that
resistance will still produce heat, and enough current for a long
enough time will produce destructive effects. The big problem occurs
when there is little rebar and lots of current. That is why it is so
important that all the rebar be well connected electrically before
being embedded, and that there be enough of it. And even if you don't
connect your rebar to the tower, if your ground is not low enough
resistance, there may still be destructive currents from the tower
steel through the concrete even with the rebar floating. The moral of
the story is that you can always add safety factor by providing more
paths to Earth to divide the current, and thus spread the heat around
while reducing the total heat produced.

Roy Lewallen wrote:
"It sounds to me as if two different things are being compared here."

At least!

Reactance prevents an in-phase relationship between voltage and current in a circuit. It also changes the impedance of a circuit. More impedance if inductance and resistance are in series, less if they are in parallel.

The phase angle is given as the angle whose tangent is X over R.

The impedance magnitude of of a series circuit is the square root of R squared plus X squared.

A simple example: 10 ohms resistance in series with 10 ohms reactance.

Tangent is 10 over 10 equals one, and the angle is 45 degrees.

Impedance is the square root of 200 and equals 14.142 ohms.

Note that the current will lag or lead the voltage in the circuit by 45 degrees depending on whether the reactance was inductive or capacitive.

The point is this circuit with only two external terminals does NOT have a voltage drop which is in-phase with the current through the circuit. Every pure resistance does have its voltage drop exactly in-phase with the current through that resistance, regardless of phase relationships in the overall circuit.

Best regards, Richard Harrison, KB5WZI

Maybe someone would like to comment on the case of two harmonic
oscillators
coupled with a capacitance. If the capacitance is large enough
(the coupling between the oscillators is great enough) the system
will have two resonances, one where the currents through
the oscillators go in the same direction,
(and the voltages across the capacitor are 180 degrees out of phase)
and one where the currents are 180 degrees out of phase (and the
voltages across the capacitor are in phase and equal).
Maybe one of you can express this better than I can, but the
phenomenon is dealt with in most undergraduate physics books.

255. Re: A collinear conundrum

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-16 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <399B167F.B6119727@eznec.com>
Source record: 182463

I just did some quick EZNEC modeling of a simple collinear. The lower element is 19.3 inches high, #12 wire. The second element begins 0.2 inches above it, and is 38.6 inches long, also #12. The frequency is 146 MHz, and perfect ground was used. The source is at the base of the lower element. As a first test, I put a second source at the center of the upper element, in phase with lower source (both are current sources). The result is a very nice pattern directed at the horizon, 8.14 dBi, with a couple of small (-20 dB) higher lobes. Next I removed the second source. This represents a two element setup with an insulator between elements. The resulting pattern is maximum at 45 degrees above the horizon, and 5.08 dBi at that angle. The gain at the horizon is 2.98 dBi, about 2 dB less than just the quarter wave element alone. So someone trying this would probably conclude that it "works", since its performance would be roughly comparable to a quarter wave whip.

Next I put a perfect, non-radiating 90 degree shorted stub between the elements. In EZNEC, this is done by adding a wire between them and putting the stub (a transmission line model) on the wire. This stub model is a true two-terminal device, since it has no common-mode current and therefore doesn't radiate or couple to the antenna. The current into one terminal is exactly the same as the current out of the other terminal. The resulting pattern is just about identical to the insulator model. This shouldn't be a surprise, since this perfect shorted 90 degree stub looks just like an open circuit across the two input terminals. A lossless resonant circuit (which is a two-terminal device with terminal characteristics exactly the same as the idealized stub) would show the same result, although it wasn't modeled.

Finally, I made a horizontal quarter wave stub using wires and put it between the elements. The stub was 20.2 inches long, 0.2 inch spacing, #12 wires. The main lobes of the resulting pattern were nearly identical to the two-source model, just 0.2 dB less in field strength. There's a very noticeable upper lobe, at about 60 degrees elevation, about 14 dB below the main lobes. This is due to radiation from the quarter wave stub. Investigation of the currents show that, unlike the non-radiating transmission line stub, the currents at the two terminals of the wire stub aren't equal in magnitude, and they're not completely out of phase. This holds true for the currents on the two stub wires for the whole length of the stub. That is, there's a common mode current along the stub.

The modeling supports what Bart has been saying: that the phasing network has to have common mode current to work. A wire stub will work because it supports this current, but a physically small lumped network (including a compacted transmission line stub) won't.

Richard,

Look at what Tom is saying. He says, a lumped constant tank can only work as the 180 degree phasing element in a collinear if it has a third terminal. Similar to baluns that need a center tap, I think. In the case of a stub, that's provided by the low impedance it has to common-mode current flow. In the case of a tank coil and cap it can be done with a quarter wave wire.

He may be the only one of us who's TRIED it. Of course, now the rest of us have to try it to see for ourselves (grin) but I think I'll do MINE at 440 or 1.2. I do know that a stub can be coiled into a circle and still work - I copied the ARRL's 3.4 wave 2-meter mobile collinear in 1970. Never DID try a resonant tank. Now I shall have to.

Earlier, Tom answered how he knows. He was asked
==========
>>OK...the discussions I've seen here (and been a part of) have offered
>>various explanations about what's going on, or what people think is
>>going on. (Or what people know MUST be going on! :-) How about some
>>_measurements_? HOW do you know that the quarter wave stub worked? HOW
>>does W8JI know that a coil with a perpendiular quarter wave wire
>>attached to its center tap works, but that the same antenna minus the
>>quarter wave wire does not give the desired collinear results?

And he answered,

>Because I built one, about 25 years ago.

>It was part of a phase I went through, when I was trying to use the

I think that's his point. FIRST, he says you can't GET 180 degrees out of a 2-terminal device. THEN he says the third terminal is provided in a stub by its low common-mode impedance. IOW, a stub isn't really a two-terminal device at resonance.

This has some interesting consequences. A _wire_ is a 2-terminal device, if it doesn't radiate.

258. ON4UN project...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-16 00:00:00 UTC
From: Fidel Leon <ea3gip@pobox.com>
Message-ID: <x1Fm5.30$qf%1.1114142@news.jazztel.es>
Source record: 182466

First of all, greetings from a new newsgroup user!

I am reading the ON4UN book, and I've been thinking about building one antenna for 160 and 80 he mentions on the book.

The antenna would be 27 meters tall, and its four *ELEVATED* radials would measure 27 meters too. The antenna would be made of 2 mm wire, and, as indicated at the book, will not have anything but the vertical element and the four radials.

For 80 meters, the system 60 degrees long, so it would be short by 120 degrees for 1/2 wavelenght. Too short -> put a capacitor, please!

For 160 meters, it would be 30 degrees long, so being short of 150 degrees for 1/2 wavelenght. Too short -> put a bigger coil!

The questions are simple... how could I calculate the right values for the capacitor and the coil needed to put the system to matched impedance?

Thanks in advance, and 73!

When you do, be sure and be careful how you determine that it "works".
There's substantial current in the upper element even if there's no
connection between elements, but the pattern and gain are quite
different than they are when the antenna is working properly.

The part about the concert career is a joke- but- the muscles in the right hand are not. I had injury to the Ulnar, Median and Radial nerves, and have lost feeling on the outer part of the hand, and almost all lateral motion (Atrophy of the interossii muscles). The grip is OK (those muscles are in the forearm). I tend to stutter on even an automatic key-HI.

I think it's more like: A _wire_ is a 2-terminal device, if it CAN'T
radiate.
It's a bit of a chicken and the egg problem and probably not worth
worrying about however.

Consider what happens if you add another 1/4 wl stub in parallel with
the first one. Orientate it so that the two stubs are radially
symmetric and perpendicular to the dipole elements. The 'third
terminal' current will now be shared between the two stubs and phased
such that the resulting radiation (from the common mode) will be
greatly reduced. In addition, the common mode impedance will be
dramatically reduced from the original 36 ohms (approx.) down to a few
ohms or less. The broadside radiation will be improved due to the
reduction in the high angle minor lobe (previously from the single
stub) and the improved current balance between the dipole elements
which result from the better 'center tap' action of the phase
inverter.

Further adjustment of the stub wire diameters and lengths can be used
to optimize phasing and radiator current sharing.

Well, I also stated in my post that I wasn't a HAM, yet... I am studying to get my ticket, and I was hoping to build this antenna so that, with minor modifications, it would work on 10 meters when I was done with it. In this way, I hope to avoid a major rebuild of the antenna when the ticket does come... I'm not running power on the base station now... I think my neighbors would get annoyed with the bleedover into their TV sets in the apartment building.

I'm trying to build the best dipole antenna I can, that will radiate as efficiently as it can, and do it once. After the accident, I don't move around as well as I used to, so I had wanted to be able to build something that would last me a very long time, be stable, and would be able to be improved when my needs change (read: when I get my HAM licence).

I hope this confusion hasn't put many people off. I didn't intend for that to happen. I was planning on overbuilding so the antenna would be able to change with my needs without massive re-working.

That makes a total of two rigs I know of which have 6 dB per S-Unit. Someone else reported the Kachina to have S-Units of this size. All other rigs I've measured, and which I've gotten reports on, have had S-units of a maximum of 5 dB (typical for some Kenwoods), and somewhat less to much less for other rigs like my Icom. The S meter typically indicates the AGC voltage, which is a more-or-less logarithmic function of the signal strength. A lot of rigs are set up for 50 microvolts for S-9, but that's a simple, one-point adjustment, and has nothing to do with the scale sensitivity and linearity. Reg's rig is the only one I've heard of which actually has an adjustment for the S meter sensitivity, and I have no idea how it's made to be constant over the scale. Unfortunately, Reg has apparently never actually measured his to ascertain whether it's adjusted correctly, or whether it's linear. (Or at least, he's never shared his measurement results with us.) There also seems to be something regional about this -- apparently only the Japanese rigs shipped to the U.K. have this adjustment, but not the ones sent to the U.S. Or maybe only the U.K. ones are adjusted properly -- this isn't entirely clear to me. It is clear, though, that meters which have never been measured are always perfectly accurate.

Thanks for the posting -- I'll add yours to the short list of rigs which actually have a 6 dB per S unit meter. You, and the Kachina users, can interpret the S unit as used by most popular writers to the marks on your meter scale. The rest of us can be seriously in error if we do that.

Wonder if you could change a component in your fs meter to work better on 80
meters also? Circuit is probably acting like a hi pass network......

How about remote mounting the antenna for the field strength meter outside
and monitoring it from the shack?

270. Comparison Review of the k2 fractal flyer

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-16 00:00:00 UTC
From: Richard Clark <rwclark@rwclark.seanet.com>
Message-ID: <G2qbOUJaVCIwJlH4mcnFdJ5cs=r9@4ax.com>
Source record: 182528

Hi All,

My page at:
http://www.qsl.net/~kb7qhc/antenna/fractal/n1ir/k2/index.htm
has been updated to follow the interests of the audience that wants to see a small antenna with positive qualities that counter balance the over-all deafness.

I have added a comparison design I call the "H Flyer." This is an extremely simple antenna having none of the twists, turns, and kinks required to fractalize a solution for the sake of fractalizing it. Three (3) wires (or five if you download the EZNEC file) rather than the Forty (40) or so for the k2. The name describes the shape which is a sloping, ends loaded dipole (or side-ways, sloping H).

So What?

The H Flyer conforms to the specifications for the k2 within a fraction of a dB or exceeds the k2 considerably. Yes it has F/B, perhaps a dB lower than the k2. It has a relatively good 10 degree radiation component (and slightly better than the k2 over-all).

So, how do we find those qualities of a fractal comparing to the H Flyer? Wide band tuning. Well here the H Flyer is easily twice the bandwidth. Small size. Actually, the H Flyer isn't as tall, merely elevated to roughly the same height - the k2 is the taller of the two (which gives it a fraction of a dB more gain at 10 deg).

With the interest of the community in low, small antennas that rely on ground to optimize key characteristics, I would propose that the "H Flyer" makes for a suitable and sometimes superior substitute of the k2. It is far easier to construct than the k2, and displays less sensitivity to minor changes in relation to earth than the k2 (although it remains relatively high). It is far more tolerant of matching. For those who wish to experiment, it appears that this design's characteristics are independent of the source's position along the slope of the vertical section. For the sake of simplicity, I chose the drive point at the lower end of the vertical section.

Excellent. I concur and have built about the same thing using 4, and
also built a vertical hung on a rope using 3 or 4 of them worked
against a ground rod and counterpoise wire. Both worked well,
although I preferred the vertical one for 160M.

I got strange looks from the kids who wondered what the ol' fool was
doing with slinkytoyz hung around a rope.....(:+}}..... But, hey,
it worked!

I could imagine 4 on a top with one as a downlead ought to work well
as and a classic inverted L or sloping L antenna with some sort of
pi or series LC tuner.

Go for it!

Source record: 182530

Hey Richard,

All you say is true! However, the voltage ACROSS the two terminal
network in the tank implementation of the collinear antenna is
immaterial as it is not responsible for driving
any current into the elements.

What is important is the phase relationship of the current going in one
side of the tank and out the other. Because it is a two terminal
network it to be in phase, otherwise electrons would be piling up in the
tank and it would EXPLODE!!!!! (Well, actually, that is a little
hyperbolic.) (c:

Gray

And to pick a nit (all out of Kwell), the parallel resonant tank
circuit, which started this thread acts as a pure resistance (except in
the limit), and whatever current actually gets through it is in phase
with the voltage across it.

And it isn't a two terminal device off of resonance, either!

If all wires were two terminal devices we wouldn't be here talking to each other, because there wouldn't be any antennas to talk about, and Mr. Hertz would be back wondering, "Well THAT was certainly boring. Wonder what happens if I put my tongue on the Leyden jar." (c:

Imagine a stub collinear of two elements driven against ground. Then imagine paralleling a bunch of 1/4 wave stubs, each perpendicular to the main elements. In the limit, this would be two disks, perpendicular to the elements joined by a circumferential piece of metal with the elements attached to their centers. Now imagine making the upper element itsy-bitsy, teeny-weeny. You've just invented the cap hat!!

I don't think any of us has any trouble understanding that even though the cap hat doesn't radiate, there is a lot of current flowing in it because of its capacitance to the rest of the world.

At least half the spacing that the manufacturers of the 6m yagi
recommend for stacking two of those yagis. For the reasons why, see my
web site.

Uh, whoa... inductor? Grid? Huh?

I was hoping to be able to figure out, in advance, how long I'd have to make the two wire halves of a verticle dipole, cut those wires, attach them to a block of some sort, feed the coax, throw it up in the air, check the SWR's, tune it and go....

Now I need to build a gamma match or something similar to get this thing to work? I had always heard that the beauty of a Dipole was its simplicity...

So now I need to ask a bunch of questions, because (and yes, I'll come right out and say it) I'm ignorant where these things are concerned..

I'm a person of meager means. I can only work 4 hours a day (not by choice), so this dipole project, which will probably exhaust me when I put it up in the air, was conceived to both save me a few dollars, let me talk on the CB farther than the four miles I get out now, and get me some limited exercise.

1. How do I measure the resistance, inductance, and/or reactance at the feed point of a dipole? I have access to a relatively decent DVOM (if Fluke is decent), an SWR meter, and that's it...

2. Will I need a degree in Electrical Engineering to, once I've figured the above out, design and build this matching bridge/gate/whatever? I'm pretty handy with a soldering iron, and I do understand basic DC and AC electronics, (heck, I've even added my own little twist to the clarifier mod in the GrantXL/148/2000 that works VERY well), but I've never done anything such as this before, dealing with things I cannot directly measure. New ground for me.

3. Would it be simpler to design an antenna that had 50 ohms resistance in the first place, without the reactance/inductance, or would it be simpler just to make up the difference once an "efficient" design was created?

I know, I'm being bothersome, and for that, I do apologise. I'm just trying to understand and learn new things.

TIA, and 73's

-SSB

As I explained earlier, it isn't the shielding that's the problem.

It's how the bring the leads into and out of the case, and how they
ground and bypass the jacks that are the problem.

You can have all the shielding in the world and one poorly routed and
bypassed lead wiill totally negate all the layers of shields.

Valid points from the previous poster. However I would be steering clear of the Icom computer controlled radios. I bought one a couple of years ago and it is a heap of shit - in other words I am not overly impressed with it's performance. I also have a winradio and it absolutely dumps all over the Icom. In the 3-4 years I have had the Icom there has been one software upgrade which didn't seem to be all that different to the original, however in the 18 months I have had my winradio there have been heaps of software upgrades. Have a look at their website - www.winradio.com
(in particular the xrs section) and have a look at what they offer, if you buy one you will not be unhappy with it. They are available in a heap of different options including internal cards and external boxes with excellent performance from all of the ones I have tried. Frequency coverage of the winradio is also superior, I have the 1500e which gives coverage from the very low part of the spectrum - from memory 50 KHz up to 1500 MHz and it offers all modes, including the digital modes. Hope you have fun,

Cheers

Matt

I have posted my current work with EZNEC (A very fine program, if you ask
me) on this dipole at http://phoenixrising.cac.net/antennas.html

I'd greatly appreciate it if someone could nab the file therein, check it
out, and see if I've missed anything and/or done anything wrong entering the

design into the program. ALL constructive comments will be greatly appreciated on this.

Thanks in advance, and 73's.

Ditto 4 times...
Have had a B'nut forever, since before the WARC bands... started @ 5 bands (10,15,20,40,80) now 8 bands (added 12,17 & 30). Been roof mounted (blew off in an ice storm!)now on the ground w 12 radials. 10,15 & 20 were better with it @ 26 feet. 40 & 30 are great with it on the ground. 80M is very narrow, to be expected for a short vertical. 40M will cover one end or the other. Full coverage possible on all the other bands.
Go for it, ground mount it and put down a decent radial system....
you'll be happy.

I am (almost) always right :-)

I almost fell for JoeOxxx, wrote the comments, then when I looked at the address it rang the bell, sure enough, Freak's another "personality."

I am just wondering about mental capacities of our "genius." I thought that by now he would be a little bit more wiser, but I guess the brain fractal grooves must be cluttered with gobledygook from the patent application. What a misleading title on the patent, he dropped other two patent applications, wonder why.

Suggestion to Freak: If you need more supporting actors/personalities go to other than AOL services, get some more names, use them to post messages to other NG to create delusion of legitimacy (careful so you don't sound like you do) and then use it on this NG. Maybe you will get away with it. (I doubt it, by now we know that only person who agrees and "supports" him is one of him.) But go ahead anyway, we enjoy your "conversations" with yourself.

Hope it helps eventually :-

Hi,
Does anyone happen to have... or know where to find a schematic for
the old (1942 or so) US Navy DU-2 200 KHz-1600KHz Loop Antenna unit?

And, perhaps, a 2nd question -- Does anyone know if there has ever
been an article on the subject of replacing the ancient 12SK7's in that
unit with transistors?

I have some buddies up here that just run a dipole around the top of
their wooden fence. They don't get great signals, but they do get on the
air. Some of the other posters mentioned the inverted V from the roof
peak which sounds good.
I live in an apartment myself and toss my 40M dipole off the balcony
into the trees on either side after dark so my neighbors won't have to
look at it. That arrangment has worked suprisingly well for me. Maybe a
little night stealth antenna action is the solution. 40M is better at
night anyway. :-)

I believe that one can get the patent and construct one of the items
for himself and not infringe on the patent as long as you do not sell the item
that you built yourself.

So, if NC can get a printout of the patent for some good drugs,
he can make a batch and take it easy. (fda may be upset with him ...)

with all the posts that nc made about lawsuits, why is his lawyer not
making the posts for him? That is what a lawyer is paid for.

gotta go and play farctal antenna games...

How precisely cut must a wire antenna be? I have heard about 1/2 wavelength wire antennas, but if the wire must be close to this length, then you can only use one band or are willing to have several different antennas. I know that tuners are intended to correct mismatches, but I have heard that performance does suffer if the mismatch to be corrected is high enough and that an even bigger mismatch can be too much for a tuner to handle.

Can anyone shed some light on this? I'm confused.

TLA is a DOS program by Dean Straw, N6BV, the editor of the ARRL Antenna Book. It provides analysis of a transmission lines and design/analysis of antenna tuners. It is bundled with the current edition ARRL Antenna Book.

A newer version for Windows called TLW will be bundled with the newest version of the Antenna book coming out soon. This version has some nifty features such as calculations on the fly which makes it much better to use.... I have had knowledge of the program (TLW) for sometime (beta tester) and can now, by Dean's permission, "let the cat out of the bag" and let you know that it is coming...

A very worthwhile program for antenna experimenters.

A good antenna matching unit can handle a lot. You could cut for the
lowest band and use a matchbox to tune on other bands. You may want to
go to open ladder line rather than coax for this however as even
harmonics of the fundamental will be feeding into a current node
(voltage peak) and coax loss can be high (well, perhaps not with
hardline!). I had a lot of grief with a vertical, a dipole, and a
folded dipole as a kid. I ended up buying a few LARGE spools of 8 ga
stranded wire - and strung several hundred feet across my parents'
property at heights varying from 30 to 50 feet. It terminated at the
far end into a chain link fence running several more hundred feet
(reasonable DC ground - not safety ground). I ran a Johnson Viking
Ranger I into this thing and worked the world with 65 watts AM and 75
watts CW. I also had one HUGE signal on 160 meters! Nothing like a
lot of wire and a good tuner!

>
>Anybody got the scoop on this?

Here's what I know about them:

The dern thing was essentially 23 feet of tubing and a BIG loading coil. Only difference between models was the size of the loading coil!

Why 23 feet? That's ~5/8 wave on 10 meters.

From what I have gathered, the loading coil was used on ALL bands. It worked on all bands, all right - you just had to go out to the antenna and change the connections to the loading coil! They never said it worked on all bands "automatically" or "without adjustment". We just assumed that's what they meant!

You also needed a ground connection - some ground rods, usually. Radials would be a lot better, of course. Coax was used because it's an unbalanced radiator. The coax shield was grounded in all cases.

On 80 and 40, the loading coil was in series with the vertical element to establish 1/4 wave resonance, and the end of the coil went to the coax center conductor. The coil's inductance was adjusted by shorting out turns with a clip lead.

Of course a base-loaded 23 foot vertical with no radials isn't the most efficient antenna in the world, but it could be made to load and it would radiate. (They never made any gain or efficiency claims, remember).

On 20 and above, the coil was connected between ground and the vertical element. The coax center conductor was tapped onto the coil a few turns above ground, and the system resonated by shorting out turns with a clip lead. By cut-and-try, you could probably find a point where the SWR wasn't too bad.

If you had a wide-range antenna tuner, you could just feed the thing directly with coax on 20 and above. The SWR would be awful, of course, but it would radiate a little! Again - they didn't make any claims for gain or efficiency. You might lose 95% of your transmitter's output in coax and ground losses, but the other 5% would get radiated.

The trick was that you had to change tap points to change bands. And the results claimed were made at the peak of the sunspot cycle, at a time when 25 watts of AM and a wet string could work the world. Those claims disappeared after a few years, when the sunspot number came down...

Earliest QST ad I can find is Feb 1953 - they sold only beams then. The verticals came along a few years later. They were still in QST in the late 1970s.

Hi Marv
Don't know anything about question #1, but re #2, I have successfully replaced 12SK7's, etc with 2N1302 hi-voltage transistors. They take up to 150V dc. I will not say even these are plentifully available. I got mine from an old board for Nixi tube displays. My tubes were in an old UK RX. I replaced them and did not have to re-adjust anything.

Hi Larry,

For a given total amount of wire on or under the ground it is always better to have more short radials than fewer long ones. (This does not apply to elevated radials).

Radial wires on the surface of the ground have a propagation velocity crudely half of the free space value. It depends on soil conductivity. But they display very low Q resonant effects so lengths are very uncritical. Make surface wires about 1/8 of the free space wavelength. Tread them down and allow the grass and weeds to grow over them. With good soil a minimum of 8 wires would not lose more than a couple of dBs with a 1/4-wave inverted-L. If there's a buried incoming domestic water pipe connect that into the ground electrode system but its not a lot better than a single wire.

Shallow buried wires have even lower velocities and resonant effects are almost absent. Lay down 8 or more wires, a spade-cut deep, which need be no longer than 1/16 or 1/20th of the free space wavelength in good soil. Don't bother with rods or plates unless you already have some for other purposes in which case include them in the ground system. You will very likely find a small number of buried radials as short as 15 or 20 feet will allow satisfactory operation on all bands from 1.8 MHz upwards. Will do very well on an 80m inverted-L.

The radials need not be uniformly distributed. They can be spread over less than 180 degrees in the general direction of the antenna wire. Use bare copper wire preferably 12 gage. Use more wires rather than longer wires.

Just put up the longest antenna wire you have room for and end-feed it via a simple L-network tuner. To gain extra length for 160 or 80m use an inverted-U, or bend the far end horizontally through a right-angle.

Download program ENDFEED from my website. It was written with just your present particular needs in mind. One small file only. Downloads in a few seconds. Not zipped up. Run immediately. It will also tell you the L or T match inductance and capacitor values for given antenna height and length.

:RatShack, but I'd really like to do this right... Is there a way to test field
:strength without said meter?

You don't need a precise meter. I have used a Rat Shack meter in the past,
and it worked fine. You are interested in obtaining maximum field strength,
not in the actual strength of the field.

Be sure to do the measuring at a fairly large distance from the antenna.
While two or three wavelengths is usually sufficient - ten is much better.
You do NOT want any near field effects interfering.

To Dan and the group.
Name here is Greg, call sign K3ANG.
A friend of mine Chuck, call sign K3FT, has been using a slinky for YEARS!!!
Here are his recommendations for the Slinky.
From an email he sent out some time ago.
Enjoy!
++++++++++++++++
I am Chuck K3FT. I currently use a SLINKY (tm) antenna at my apartment and operate 80 - 10 meters with it. My cost? approximately $ 8.00 for the four Slinkies (tm) (yes it's a trademarked name, believe it or not! HI), about 20 bucks for RG8X type cable and a couple of bux for incidentials. That was about it. In other words, I operate 80 - 10 meters with a Slinky(tm) antenna mounted on my apartment balcony outside and it cost me about 25 - 30 bux total INCLUDING COAX! It's not the neatest and prettiest to look at.. but it fulfills three venerable Amateur Radio dictums - It's cheap, it works, and I built it so I learned something and had fun doing so.

You can duplicate your own for LOTS less than the 40 bux he's asking (plus shipping) AND you can probably get coax too. SO you have a complete system and you built it yourself!

TO ACQUIRE

First, go to WALMART or any other larger store. Slinkies sell for about $1.99 each. Best to call the store and ask. Sometimes they run out AND sometimes they stock the plastic ones. Make sure you get the metal Slinky! Check first - save the driving. Buy FOUR of these. Cost - about $8.40 including tax. (why four? AHH! Stay tuned, boys and girls! You'll see!)

Second, grab a piece of scrap wood/plexiglass(tm)/LEXAN(tm) or similiar material. It should be rectangular about 6" - 8" by 1" or so. Not picky on size, it's used as a center support for the dipole. The 1" is for wood, if you use plexiglass/LEXAN it will be narrower. It has to be wide enough to take a screw eye that will be used for a center support point, but that's about it. If it's wood, paint it with something to protect it. If plastic, leave it alone. Cost - about zero. (Total cost so far - about $8.40)

Third, get some stranded wire with insulation. #18 or so will work. You need 4 feet. Cut into two equal length pieces. Strip each end. This is used to connect the SO239 connector to the antenna ends using delta matching techniques. Total cost still about $8.40 unless you bought wire and plexiglass/lexan.

Fourth, get an SO239 bulkhead mount female coaxial connector. Scrounge one. If you have to buy one they are about $2 new or so. Total cost now (if bought) about $11.00.

Your total cost for all new should be now around $11 or so. Maybe a little more if you bought some of the things that most of us have lying around. However, it's still a lot less than the 40 bux plus shipping he'll get.

BUILDING it.

First, take two Slinkies (tm). Clean both ends of EACH Slinky very well with alcohol or other suitable cleaner to remove oxides, greases, oils. Rough up the flat surfaces with some sandpaper, file, etc. Reclean. Take a LARGE WATTAGE soldering gun or torch and tin the cleaned end of each Slinky with solder. It will discolor, but no big deal. Just tin it well. You will end up with eight tinned ends - two ends for each Slinky. Place the flat side of the tinned end of one Slinky against the flat side of the tinned free end of another Slinky so that it makes ONE continuous coil with the turns going in the same direction.

Second, wrap some copper wire around the mated ends so they are secured, mechanically, to each other. Solder them together and wrap with electrical tape or some othe kind of covering. Do the same with the other two Slinkies. YOu will end up with 2 LONG Slinkies.

Third, get 2 medium sized alligator clips and solder one onto each end of the previously stripped ends of the two pieces of insulated stranded wire. You will have two wires, each having an alligator clip on one end. Cover these soldered joints with protective material (electrical tape, etc) You will end up with two pieces of equal length insulated stranded wire with an alligator clip at one end of each piece convered by protective material.

Fourth, clean the center pin AND one corner hole of the SO239. Tin these cleaned points. Solder one end of the already stripped insulated stranded alligator clip wire to the center pin of the SO239 and the other alligator clip wire to the tinned corner hole of the SO239. Cover the backside of the SO239 with protective material. Center and mount the SO239 on the flat side of the center support material. Orient it so that the SO239 center pin is pointed towards the center of the support. SECURE the SO239 to the center support. MAKE SURE IT IS WELL AND TIGHTLY SECURED SO IT WILL NOT MOVE!!!!

Fifth, take the center material (wood/plexiglass/LEXAN) and mount two eyebolts into the flat side - one on each side of the already mounted SO239. Make sure the eyebolt is located on the same side as the SO239 connector. Space each one about 2" - 3" from each side of the SO239. Secure the eyebolt with a nut. Install a screw eye into the top narrow part of the center support so as to provide a place to hang/attach the dipole center support to a wall hook, branch, or other center support. YOU MUST PROVIDE CENTER SUPPORT FOR THE DIPOLE!!!!!

Fourth, clean the eyebolts with cleaner. Take the SO239 and clean and tin one of the holes in the corner of the connector. On the backside of the SO239 connector, solder one end of the previously prepared piece of insulated stranded wire with an alligator clip to the center pin of the SO239. Solder the other piece to the tinned hole in the corner. Cover the backside with something to protect it from the elements. Secure the SO239 assembly BETWEEN the eyebolts so it is mechanically secure. This can be done with tiewraps or any method you like. THE KEY IS MAKE SURE THE SO239 is REALLY SECURE and UNMOVEABLE.

Fifth, take a free end from each doubled up Slinky and carefully bend this end of each Slinky around the eyebolt. One turn or two is all you need. Crimp it so it makes as good a mechanical connection as it can be. Solder it REALLY WELL. Cover the connection with some covering material to protectc it.

What you now have is this...

1) Two Slinkies soldered together on each side to make a doubled up LONG SLINKY. An end of each doubled up Slinky is soldered to an eyebolt. There is an unused eyebolt that acts as a connection point to hang the center support. The other end of each Slinky leg is free and can be slipped through a support loop, bent into a loop and hooked over a branch, hook, whatever floats your boat.(Just make sure it's insulated!) The two wires from the SO239 hang free and are terminated in alligator clips.

THATS THE WHOLE ANTENNA! Total cost- about 12 bux or so. All you have to do is make sure the SO239 is secured well to the center support material. Make sure that the center pin of the SO239 goes to one free hanging wire/clip and the corner hole of the SO239 goes to the other free hanging wire/clip. THAT'S IT! You now have a dipole that will work 80 - 10 meters with a tuner.

TUNING and USE

If you have an antenna analyzer like the MFJ249/259 (worth their weight in PLATINUM!!!!) you can hang the dipole up and check the SWR at the center conductor. Stretch out the dipole and hang it up. Stretch it out as far as you can and route the antenna as best you can. Go out from the center of the dipole on one side and clean the Slinky turn at your chosen point. Clip the alligator clip from one wire to this point. Find the other same exact turn location on the other Slinky side and do the same for the other wire/clip.

Check the SWR on the bands of interest. If you can tune it, go for it and enjoy! If you have an antenna analyzer sweep the bands and note the resonant points. Play with the clip/Slinky coil points until you find resonant points in the band(s) of interest.

Once you have the tap point located, mark and/or permanently attach the clips. I leave mine free to move and just protect them from the elements so I can adapt to different configurations. Odds are you will find a point where you can tap the antenna permenantly and, with the

tuner, tune all the HF bands. I do and it works passably. It gets you on the air and squirts RF out and you can make contacts.

RESULTS

It took me about 1 hour to build this antenna. I spent, including coax about 25 bux. I mounted it following the perimeter of my balcony so it bends and snakes about a bit. It is about 25 feet off the ground. I work consistently around the east coast and have worked DX too as well as out to the Midwest USA. Yes, it's inefficient, yes you need to have a ground system (You DO have a ground system, I trust! HI) and it's a compromise. BUT it makes a good emergency antenna, apartment antenna, or just one that can be coiled up and put in a small box for 'being there when you need it!'. Plus it's just fun to 'speriment! HI.

TECHNICAL NOTES

The Slinky coil is about 2.5" in diameter. You stretch 'em out so each turn is about 2.5" apart (give or take). Figure the # of turns times the diameter will give you the length in feet. Two Slinkies per side is about 90 some odd feet or more total length. The movement of the alligator clips towards or away from the center point is 'delta matching' the antenna so as to achieve a match to the transmitter. This is best found by doing. Make sure you have some kind of ground for your station. This will affect the operation of the antenna as well as minimize radiation problems with TVI/RFI, etc.

When you are finished using the Slinky dipole, just unhook the free outer ends, let it coil itself up into a nice tight coil and voila! instant portable antenna!

NOTE! The slinky WILL RUST if left out in the elements. You can protect it by spraying it with Krylon CLEAR lacquer or some other type of protective coating. I didn't do mine and it lasted about 3 months before surface rust appeared. It still functions, but I must replace it within a year or so from now. Just a warning note.

Enjoy! 73 Chuck K3FT

contact me at k3ft@erols.com for info, questions, suggestions. I use the Slinky most every night andyou can find me on MDD on 3643 Khz at 0000Z and 0300Z. I also listen to 146.07/.67 W3FT repeater when I'm home.

Source record: 182602

Geez Richard, I don't know. But I think you can get a
broader match with a 50 ohm resistor at the end of
the coax. Suspend it inside half a tennis ball which is
lined with copper, and you'd probably get a pretty
good F/B ratio. You'd certainly have small space,
and might not be impacted by the environment. I've
actually worked people off a dummy load - amazingly
both of us heard each other. I can't claim DXCC
that way - more like QVDLIYGA (QSO - Very Damn
Lucky If You Get Any).

What's left? Gain. I can't control the 100+ db
attenuation at distance - all I can try to control
is how much signal I can collect (or radiate)
at my location, and the direction I want my
"signal collector/radiator" to favor. Q - maybe
I can make the collector real narrow with
a better S/N ratio - but the Fractal apparently
is pretty broad.

I may be forced to try to build one of these
things just to satisfy myself. The tennis ball
contraptuion will be easy by comparison.
But how would a "real" antenna compete?
Suppose you went vertical with a slinky,
occupying the same height as the Fractal.
I *assume* you could match it at 50 ohms
by selecting the right points on the slinky.
I haven't done it so I don't know. But
overall, wouldn't that be a more effective
antenna on say 20 meters than a Fractal,
even with no F/B on the slinky? You could
even add another slinky within the .2
wavelength box as a director or reflector.
I dunno - maybe you couldn't stretch the slinky
far enough within 1/8 wave to make it play.
Certainly the slinky idea is physically far
easier to implement than the fractal - whether
it would outperform the fractal is beyond me.
Heck - maybe a 1/8 wave whip with loading
coil and radials would outperform the Fractal,
at the cost of no F/B. After all, you can
squeeze an awful lot of distance out of a very
small vertical - I'm thinking of 80 meters mobile.
Maybe the REAL test of a Fractal is in a mobile,

where small height is real important.

I just don't know. Worse, I want to build one of
these things so I can understand their performance
first hand. But I don't know how. I can't figure
out the element lengths nor the X-Y-Z angles
between the elements. I'm afraid someone
brighter than me will have to publish that information
if I am to be able to build one.

But - on the plus side - your post and diagram
are GREAT. At least now I am beginning to learn
something about these beasts, which is what I've
been trying to do for quite some time. I may be
missing a lot here, but whatever I am getting is
directly as a result of your help. And I really
appreciate that. Thanks!

Chip, that's a great idea. He has no antenna now, so the K2 would
guarantee him GREAT comparative performance and earn you the
kudos you want for the antenna. So I propose this: send him the
antenna, along with whatever instructions he needs to put it up, if
he agrees to the idea,and is willing to post his opinion of the
antenna. Then we can all read how well he makes out
on the bands. We will be getting a second ham's opinion of the
antenna, you will be getting the credit that should be associated
with it.

To avoid any cost to you, I'll pay the postage, which I assume
will be well under fifty dollars. I'll go that high, if you and he agree.
Reach agreement here on the NG. Weigh the antenna, and find
out what it will cost to send it to him, post that figure here.
I'll send you a money order for that amount, up to fifty dollars.
When you have the money order in hand, send the antenna to
him. This is not a commercial transaction - neither he nor I am
buying anything from you. It is an experiment, which would
incur expense, and it is that expense that I am addressing.

What say?

```
: So your saying that tuning an antenna with a swr meter is wrong ..max field
: strength does not guarantee lowest swr .. how can you go wrong by tuningan
: antenna for lowest swr

Here are a couple of examples.

A dummy load has an SWR of 1:1, but it makes a lousy antenna.

Many antennas, without matching networks, are not 50 ohms - matter of fact,
most are not. Now, an antenna radiates the most power when resonant. Let
us assume that the antenna is 25 ohms when resonant. That means, to radiate
the most power, you need to tune for a 2:1 SWR - not 1:1. But how can you
tell this from tuning the antenna to a 100 ohm impedance - which would also
produce that 2:1 SWR? That would be even further from resonace.

In short, SWR meters and field strength meters work well together, but the
SWR meter is necessary only to make sure that your transmitter can couple
safely into the load. Field strength is all that matters - you don't
transmit SWR.

The question was how do you measure impedance.
An swr meter does not measure impedance. An swr
meter (more properly, VSWR meter) measures a
ratio of the voltage in the forward direction (ie out
to the antenna) versus the voltage in the backward
direction (ie back into the transmitter, reflected from
the antenna). The bigger the reflected voltage, the
higher the swr. An swr meter, nevertheless, is a good
indicator of whether impedance is matched at 50 ohms,
as you pointed out. It is certainly not the best.

But impedance consists of 3 elements - capacitive
reactance, inductive reactance and resistance.
A true impedance measurement would be expressed
as so many ohms, not as a ratio. And, typically,
one would find expressions that look something like
this: 23 +14 Jx That reading indicates the the
complex impedance consists of 23 ohms resistance
plus 14 ohms inductive reactance. If the expression
were 23 -14 Jx it would mean 23 ohms resistance
plus 14 ohms capacitive reactance.

Now, why is this important? Because you want all
of the power going out to the antenna to "see"
nothing but resistance. In the case of an antenna
with 23 ohms resistance plus 14 ohms inductive
reactance (23 + 14Jx), the only power radiated
by the antenna is the power across the 23 ohms
resistance. The power across the 14 ohms inductive
reactance is wasted. So - you want to get rid of
that +14 Jx, even if it leaves you with 23 ohms,
and an swr worse than 2:1. Why? Simple.
You transform the 23 ohms to 50 ohms. Now there
is no reflected voltage (no reflected power when there
is no reflected voltage) and all of the power reaching
the antenna is radiated, rather than having some of
it wasted in Jx. There are a number of ways to
transform the impedance, at the antenna, to achieve
the maximum radiation of the available power. Pruning
the antenna (cutting the wires smaller and smaller while
observing the swr reading getting closer and closer to 1.1
to 1) is one example. In a beam antenna (which would
have an impedance in the low to mid 20's with some
Jx reactance as in teh example expressions I used) a

typical transformation AND elimination of the Jx is
accomplished with a gamma match. A gamma match
includes a transmission line transformer (which introduces
+ Jx (inductance) AND transforms the resistance from
23 ohms to 50 ohms) and a capacitor. The capacitor
introduces -Jx. The +Jx is unavoidable, as it is necessary
to attach the feed line to the center of the element and to
some point away from the center to achieve 50 ohms
resistance. The length of wire that allows attaching the
center conductor of the feed line (the shield is attached
at the center) to the 50 ohm point somewhere out on
the element away from the center introduces the extra
inductance - the +Jx. Now, if you have an accurate
impedance measurement and know how much inductive
reactance has been added to get to 50 ohms resistance,
you can compute the value of capacitance needed to
produce an equal amount of - Jx. Finally, in all cases
above where the term resistance was used, the correct
term is radiation resistance. I won't get into a discussion
of that here, other than to say that it indicates that the
signal it (the radiation resistance) "sees" is the signal
it radiates out of the antenna. It is not the same as
the resistance we talk about at the electronic component
level, The signals those resistances "see" are converted
to heat, not radiated.

That is important stuff if you want to really make your
antennas perform well. The simplest concept is this:
you can get a good match (ie swr is 1.1 to 1) and have
a lousy radiator. If you had, for example, 1 ohm of
radiation resistance plus 49 ohms of inductive reactance, then
most of your signal would be converted to heat in the
inductor - only about 2 percent would be radiated.
Clearly, you would want it to be the other way around!
So, that's why there needs to be a distinction made
that swr meters do not measure impedance.

316. Antenna from ON4UN book!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-16 23:06:00 UTC
From: Fidel Leon <ea3gip@pobox.com>
Message-ID: <y8Fm5.31$qf%1.1704019@news.jazztel.es>
Source record: 182534

First of all, greetings from a new newsgroup list user!

I am reading the ON4UN book, and I've been thinking about building one antenna for 160 and 80 he mentions on the book.

The antenna would be 27 meters tall, and its four *elevated* radials would measure 27 meters too. All the antenna would be made of 2 mm wire. The antenna schema at the book does not speak about something more to be put at the antenna (not top loading or so on).

For 80 meters, the system would be 60 degrees long, so it's short by 120 degrees for 1/2 wavelenght. Too short-> put a coil, please!

For 160 meters, it would be 30 degrees long, so being short of 150 degrees for 1/2 wavelenght. Too short -> put a bigger coil!

The questions are simple... how could I calculate the right values for the capacitor and the coil needed to put the system to matched impedance?

Thanks in advance, and 73!

Fidel Leon - EA3GIP

318. SWR Meter for LW & VLF

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-17 00:00:00 UTC
From: mthompson14@yahoo.com
Message-ID: <399c0329.14827743@news-server>
Source record: 182469

Hello,

Can anyone help me on how I would go about making an SWR meter for the VLF and LW range. I have a radio shack SWR that is good over 3-30 Mhz, with one watt applied but is it possible to make one with a freq range of say 1Khz to 500Khz? With less then a watt applied power?

Thanks
Mike T.

This is very true. I made the mistake of building a
step attenuator and using it to check the accuracy of the S
meter on my Japanese rig. I haven't been able to trust that dang
S meter since.

All of what you say is true, too, Bart! However, it is not the voltage ACROSS the tank circuit that is responsible for driving the current into the antenna.

In this sub-thread there was a question as to whether the current through the tank was phase shifted, followed by a subsequent discussion of the phase relationship between the voltage and the current in the tank circuit. It is important to note that, while it the voltage across the tank may indeed be shifted in phase relative to the current through the tank, this does not imply that there has been any phase shift in the current, and, because the voltage ACROSS the tank isn't responsible for driving the current in the upper element, its phase relative to the current is immaterial.

Have I got that right?

Gray

At least in the earlier ARRL Handbooks there is a resistive bridge for VSWR- these work well for freq up thru UHF if properly laid out. Very sensitive. They are absorptive, so cannot be left in line.

The ones I see at my local Rat-Shack are made by Amphenol, and use Teflon
dielectric. These are a problem at high power levels?

> Anyone using N connectors in QRO applications is asking for trouble.
> Especially if SWR might ever get high.

I remember a thread, on this NG, some months back about how much power a "N"
connector can handle. I don't recall anyone ever finding a spec for a given
manufacture's connector.

But it is...

Assume the voltage at the top of the lower dipole element is known.

Determine the current which must flow between the upper radiator and the phase inverter. This current can be directly computed from the required power flow between the lower and upper elements once the voltage is known with respect to the 'third terminal reference'.

Determine the current which must flow between the phase inverter and the upper element. We have already covered the polarity; the optimum magnitude depends on the impedance of the upper radiator but will likely be comparable to the current 'extracted' from the lower element.

The required current (complex) into the upper element is now known. The voltage required to force the required current into the upper radiator is simply the current times the endpoint feed impedance with respect to the 'third terminal reference'. Computation of the endpoint feed impedance requires knowledge of the conductor dimensions and the mutual impedance with the lower element along with various environmental factors.

The input voltage, output voltage, input current and output current, all complex quantities, are now known. The objective is to design a phase inverter which meets all four constraints, or at least comes close enough.

Establishing the correct difference between the input voltage and output voltage of the phase inverter is the primary design objective of the phase inverter.

The voltage across the phase inverter is what forces the current in the upper element to the correct magnitude and phase.

This isn`t something you would do with a slotted (trough) line or even Lecher wires. The wavelength is too long.

The problem of determinig impedance, reflection, matching, or whatever you are up to is simplified by wavelengths which are long compared with the electrical parts you can use.

You would do well to get a copy of "Test Equipment for the Rafio Amateur" by H.L. Gibson, G2BUP, and published by the Radio Society of Great Britain. ARRL may resell these in the U.S.A..

There are probably several ways to get the information SWR might provide. The recommended book would give some ideas as to the complexities of the possibilities.

Trying to purchase a new house without Antenna restrictions or covenants is really difficult and
I'm a little bit confused on the FCC policies concerning the private contractual agreements.
(I snipped the FCC's comments on a petition that was presented by the ARRL)

I was told by a real-estate agent that restrictions and covenants are similar to leans against the property and
are held as public record at the County Dead Office. They are not signed by or agreed to by persons that
purchase the property. They are adopted by the land developers and I guess you can that they are policed
by the Home Owners Associations!

If I purchase the property and pay cash for it but I don't sign the covenant or agreement. How can that be an
agreement between two parties and how can I be restricted by the covenants?

Washington, D.C. 20554

In the Matter of)
)

Modification and Clarification of Policies and)
Procedures Governing Siting and Maintenance) RM-8763
of Amateur Radio Antennas and Support)
Structures, and Amendment of Section 97.15)
of the Commission's Rules Governing the)
Amateur Radio Service.)

ORDER

Adopted: November 18, 1999 Released: November 19, 1999
By the Deputy Chief, Wireless Telecommunications Bureau:

-----SNIP---------
-----SNIP---------

III. Discussion
6. The Commission's policy with respect to restrictive covenants is clearly stated in the MO&O establishing a limited preemption of state and local

regulations. In the MO&O, the Commission stated that PRB-1 does not reach restrictive covenants in private contractual agreements.17 The Petitioner argues
that enforcement of a covenant by the court constitutes "state action", thus converting what otherwise would be a private matter into a matter of state regulation and, thus, subject to the Commission's limited preemption policy.18
Notwithstanding the clear policy statement that was set forth in PRB-1 excluding restrictive covenants in private contractual agreements as being outside the reach of our limited preemption,19 we nevertheless strongly encourage associations of homeowners and private contracting parties to follow
the principle of reasonable accommodation and to apply it to any and all instances of amateur service communications where they may be involved. Although we do not hesitate to offer such encouragement, we are not persuaded
by the Petition or the comments in support thereof that specific rule provisions bringing the private restrictive covenants within the ambit of PRB-1
are necessary or appropriate at this time. Having reached this conclusion, we
need not resolve the issue of whether, or under what circumstances, judicial enforcement of private covenants would constitute "state action."

I have looked at some of the replies......can I suggest that an SWR meter is not going to be a lot of use.....very few aerials are 50ohms. and most of the resistance in LF aerials is ground loss. A simple bridge is probably more use. Noise bridges have been modified for LF quite successfully......see the links on the LWCA and AMRAD sites for some good info.

I wish I could know that something would work just because I built it. Unfortunately, my skills are of an inferior sort, and I generally have to fire it up and test it after I build it to make sure it works. I don't at all doubt THAT Tom's collinear worked with coils with pendant 1/4 waves and not without them, I'm just looking for some practical tests that reasonably prove whether a given collinear implementation is working or not. I, too, have built collinears, and my tests have told me that they work sensibly as the simulation beforehand told me they would.

Thanks to Roy for the simulation work he did & posted on this. To me, it's clear that a simple two-terminal network won't do for coupling the end elements to the driven element, and I'm not surprised that the perpendicular quarter wave stub DOES work. But it's not clear to me just how well the coils typically used in, for example, the cell phone car antennas do their purported job. Those coils are generally a significant fraction of a wavelength long...one I measured this morning is rougly 1/8 wave long, and a significant diameter. Same with a commercial 440 antenna I have that purports to be a collinear. That's large enough, and the coil is near enough to the fields of the driven element, that I can imagine that it does SOMETHING more than just a two-terminal network. Indeed, it at least serves to space the coupled element significantly further from the driven element, lowering the mutual impedance between those two. -- I wonder if NEC could do a reasonable job on a straight-line segmented approximation of such a coil, maybe with "square" turns, spaced about 4 wire diameters turn-to-turn.

Cheers,
Tom

Let's see here... "current...is retarded by 180 degrees." So...there
are two terminals of the stub that connect to the driven element and the
collinear undriven element. Let's say that current goes into one the
one connected to the driven element. That means that, with the 180
degree retardation, current also goes into the one connected to the
collinear element. But now what you have is not transmission line
currents, but common mode currents, on the stub. Do you think that's
what happens? It's not what Roy's simulation tells us, and it's not
consistent with what I read in books I trust on the subject: they
both say that there is a SMALL common mode (antenna) current on the
stub, and a relatively LARGE excitation of the transmission line
currents, causing a LARGE voltage drop across the open end of the
stub. Indeed, in that case, the current in one wire of the stub is
very nearly equal to the current out of the other wire, but not
exactly equal.

Cheers,
Tom

Something that I think is being missed here... in a collinear with currents in the upper and lower element like we want them for gain, the currents are in phase. When the current is top-to-bottom in one element, we want it top-to-bottom in the other element. What you actually get in an antenna where you replace the phasing stub (or whatever) by a straight wire--in other words, just connect the collinear element to the driven element--is current that goes _nearly_ to zero (but not quite) at that junction, and a short distance away is essentially 180 degrees out of phase with the current in the other element. So, in effect, having NO "phase-inverting" network at that point results in a phase inversion. In fact, if you replace the connection with a short gap, an insulator, you STILL get that phase inversion from the driven to the collinear element.

How DO you get the phases to be the same? You must provide excitation of the mode where the currents are the same phase (direction) in both elements, and enough excitation to overcome the excitation that results from the mutual impedance between the two elements. Now, consider that there is some magnetic coupling and some capacitive coupling from one element to the next, and together they result in the mutual impedance. WHAT IF you could arrange to put a high voltage between the adjacent ends? Yes, that's the voltage that Bart has been talking about, and that Gray (sorry Gray) suggested might not matter. If there's a high voltage, that high voltage will cause a current in the capacitance that exists between the adjacent ends of the elements, and THAT CURRENT _must_ flow in the ends of the wires, connecting to that voltage source. Draw it out, and you'll see that you then end up with current in the same direction in each element, which is just what you want for collinear gain. So if you can make the voltage high enough between the ends, you will force the mode you want.

How do you get that voltage? One way is with the quarter wave stub which couples to the field of the driven antenna in a way that transmission line currents are excited on it. One way to NOT do it is to put a resonant tank there which does not couple to the field of the antenna. One way to NOT do it is to make the quarter wave stub collinear/coaxial with one of the antenna elements. But...if you use a coil which is physically large and arranged properly (if there is such an orientation) to couple to the driven element, that MAY give reasonable collinear performance.

Cheers,
Tom

340. Re: A collinear conundrum

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-17 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <399C4A9C.362C03F6@eznec.com>
Source record: 182491

For 1 amp at zero degrees at the base of the antenna, EZNEC shows the current into the lower stub wire as 0.265 amps at -115.5 degrees, and into the upper wire as 0.363 amps at -55.9 degrees. Unless I did the math wrong (a distinct possibility), this represents a differential mode current of 0.162 amps and a common mode current of 0.274 amps. Notice that the currents are only 60 degrees apart, nowhere near the 180 degrees of pure differential mode current.

For anyone else interested in doing this simulation, be sure to pay attention to the direction of current flow and how you've defined your wires. Positive current flow in all MININEC and NEC-2 programs is defined as being in the direction from end 1 to end 2 of the wire. It's easy to get an inadvertent and spurious apparent 180 degree shift if you're not careful.

Jack:

The covenants became part of the deed when it was filed with the county. When you purchase the property, you purchase the deed, and the covenants go along with it. A lawyer would word that differently, but that's basically how it works. You cannot claim that you didn't agree to the covenants; you have joined in the agreement.

Be careful about what real estate agents tell you. When I purchased my current house about four years ago, I found that I knew MANY things about property sale and ownership that the realtors didn't know. I had considerable difficulty explaining the issues of antennas and covenants to my agent. And on a different issue of liability and insurance, I finally had to tell the skeptical agents (mine and the seller's) that what I was telling them was correct and that I had to have things my way. When we got to the settlement with a lawyer presiding, the seller's agent asked about what I had told them, and the lawyer said "Of course". The agents were much surprised and asked me not to tell anyone about it (really!).

Don't try to be your own lawyer, and don't accept that realtors know the law -- not even property-related law.

Looks reasonable to me.

The voltage at the lower stub wire should be around -90 degrees with
respect to the excitation current. The difference between the voltage
phase and the current phase is the phase angle of the power transfer
from the lower element into the phase inverter. I believe the minimum
common mode current, and therefore stub radiation, occurs when the
phase inverter input and output phase angles are both zero.

Check out the FCC's Web page. The Commission has preempted both CC&R's and zoning where they prevent reception of over-the-air television signals. It has done so for antennas which mount either on an owners property, or in the area of which a renter has use by reason of his tenancy.

However, the preemption extends to antennas which (If I recall correctly) extend no more than 12 feet above the roof line. An attorney acquaintance of mine, who is with the ARRL volunteer counsel program, tells me you will have to actually show the antenna has use for television to avail yourself of the preemption. He was not acting as my attorney at the time, and I am not an attorney either; this is naturally NOT legal advice.

But it may hold out some hope for you.

Cheers,

Cortland

Why do you say "The MOV type will NOT work"?
Do you think gas discharge tubes will *always*
save the computer? If not, what limits do you
think apply? At what voltage do they begin
to conduct? What current carrying capability can
be obtained in the gas discharge tubes you have
in mind? For gas discharge protection, what
kind of ground is needed, if any? Are gas
discharge tubes used for common mode protection,
differential mode protection, or both?
Thanks!

I don't have the answer -- this legal stuff is way over my head -- but
in the latest QST, the September issue, on pages 87 and 88, the
"Washington Mailbox" section, there's two pages of info attempting to
clarify what protections a home buyer/owner has or does not have under
PRB-1. This info might also be accessible at the ARRL web site if
you're a member.

Ok.

> But now what you have is not transmission line
> currents, but common mode currents, on the stub.

The total current on the two (upper and lower) stub wires is the sum
of the differential mode and common mode currents.

Assuming the stub is lossless in the differential mode, the
differential mode current will be zero at the terminals and increase
sinusoidially to a maximum at the short. The magnitude of the current
in the short will be the terminal voltage divided by the
characteristic impedance of the differential mode.

The common mode current will be minimum at the shorted end and
increase nearly sinusoidially to maximum at the terminals.

> Do you think that's
> what happens? It's not what Roy's simulation tells us, and it's not
> consistent with what I read in books I trust on the subject: they
> both say that there is a SMALL common mode (antenna) current on the
> stub, and a relatively LARGE excitation of the transmission line
> currents, causing a LARGE voltage drop across the open end of the
> stub.

The ratio of peak common mode to differential mode current is
dependent on the feedpoint impedance of the upper element, and the
differential and common mode characteristic impedances of the stub.
The ratio can be juggled to some extent in the interest of improving
structural integrity, maximizing bandwidth and minimizing losses. All
else being equal, the differential mode currents should be minimized
to reduce the total reactive power. The common mode characteristic
impedance is not as important since it has little effect on common
mode current near resonance. These effects drive to optimization
towards small diameter conductors with large spacing. The optimum
point is reached when the current in the short begins to detract from
the broadside gain.

> Indeed, in that case, the current in one wire of the stub is
> very nearly equal to the current out of the other wire, but not
> exactly equal.

I believe Roy's simulation illustrates exactly what you are
describing.

Good advice. There's another serious mistake I see people making when it comes to lawyers. A lawyer might be present at the closing, or otherwise involved in the sale, and people sometimes mistakenly assume that his or her legal advice should be followed. That's not how it works. If *you* hire a lawyer, that lawyer's job is to look out for *your* interests and no one else's. Similarly, a lawyer hired by the seller, realtor, lender, or someone else is looking out solely for his or her *client's* interests, not yours. These may be at complete odds with your interests. So if legal advice is needed, hire your own lawyer to watch out for your interests, and don't think for a minute that anyone else's lawyer will do that.

It's always seemed to me a good investment to spend a few hundred dollars for a lawyer before I sign away a couple of hundred thousand on the dotted line. But most people don't seem to see it that way. I also found it to be very worthwhile to spend a day or so at the courthouse looking at the public documents relating to the property in question. Seemed like a small price to pay for added assurance I wasn't going to be making a bad mistake when I agreed to pay all that money.

Are you referring to the double peaked response characteristic of a
cascade of two overcoupled resonators? Tuned IF transformers are a
classic example. The effect is also important in the design of Yagi and
other parasitic antennas. Interestingly, the effect is desired, but
seldom achieved in the so called double Bazooka antenna where shorted
1/4 wl stubs are placed in parallel with the feedpoint of a 1/2wl dipole
in an attempt to broadband the antenna.

Good question, but a bit off topic for this thread. I respectfully
suggest you either wait and see if this thread progresses to the point
where optimization of the phase inverter is being discussed or perhaps
begin another thread.

IMHO, the double bazooka would be an excellent topic for discussion in
this forum.

>
> Tom Donaly KA6RUH

Tom must be busy having a life, so I'll take a shot at this question if you don't mind. What you'd need in order to make an accurate S meter (and by this I mean an S meter in which the divisions are an equal and known number of dB apart) is to have the AGC voltage be a truly logarithmic function of the input signal level. This would have to hold over a wide range of signal levels. If I were designing a receiver today to do this, I'd probably begin by looking into some of the log amps available from Analog Devices. Using one in a feedback loop might do the job. Doing it any other way wouldn't be easy. Although a crudely logarithmic function is easy to come up with, one which is truly logarithmic over a wide range, and reasonably temperature stable, isn't. Spectrum analyzers have a logarithmic response over a wide range -- if you think it's simple, take a look at the log amp schematics for a spectrum analyzer.

Consider the fact that receiver manufacturers have been producing receivers for decades which don't have 6 dB per S unit. And their customers frankly don't care. I strongly doubt that an accurate S meter (meaning one with a known and constant number of dB per division) would sell a half dozen more receivers -- in fact, a 6 dB-per-S-unit meter would be regarded as being "dead", and might well inhibit sales. So what incentive do receiver manufacturers have for going to the expense of making a 6 dB per unit S meter? None at all.

N7GSU QSLs will design custom, high-quality, color QSLs for a flat $30. The designs are sent to you in PDF format and maybe printed as needed using your color printer and readily available card stock.

If you are a member of FISTS, FISTS Northwest, FISTS New England CW Club or QCWA - I have in stock designs that can be customized with your info for only $15.

If you are planning a special event or DXpedition, you owe it to yourself to check into having me design that special, custom QSL for you. If your club doesn't have a logo, needs a club QSL design for it's members, or wants to sponsor an operating award; let me design these for you! Custom QSLs are a flat $30, logo designs and custom award certificates average $30-$50. This includes designs incorporating color photos!

Payment can be accepted by Visa or Mastercard, or by email via PayPal. I also accept checks and MO's. Checkout the website at:

http://www.n7gsu.com and see what I can do. The site is still under construction, but new content is being added daily. If you have an idea you'd like turned into a custom QSL, logo or award certificate... give me a try!

Tom and Bart,

I concede to superior analytical powers!

I was considering the voltage referenced to the elusive third terminal as the (electro)motive force that drives the current into the upper element. But as Bart pointed out to me in an off-NG conversation, the thing about voltage references is that, as long as you are careful in the math, the reference point can be moved around. Since the voltage at the upper end of the lower element can be referenced to the third terminal and since one can reference the voltage at the bottom of the upper element to the same point, it is only an intellectual hop, skip and jump to defining the current in the upper element in terms of the voltage across the gizmo, whatever it may be.

Thanks for the clarification.

Or you can do it all in DSP like my W-J HF-1000.

I haven't verified it's signal strength meter performance, but it is unabashedly calibrated in dBm (with S-units superimposed). Considering W-J's reputation, I suspect it is pretty accurate.

N connectors, below about 400 MHz, are a waste unless you have a whole
bunch of connectors in the line or are doing precision measurements.

They handle less power than a UHF connector, and are more difficult to
install and depend heavily on shield strength to stay put.

PL-259's aren't as waterproof, so you have to be careful, but they fit
the LMR400 cable without problem.

Amazing. The 756 I had was a mile off. The scale wasn't even close to correct at the low end, although with the preamp off it was about 55 microvolts at S 9.

Once in a while a certain rig of a certain model pops up that apparently is accurate. Too bad the manufacturers can make most of them that way.

I've got 7 radios sitting here in this room, and not one is correct. Most of them don't even have the scale marked "correctly", and because of that can NEVER be calibrated to anything other than 5 dB or less per S unit.

Shame on Icom and Drake for being so stupid they marked the scales wrong, having the same change in meter current below S-9 being 5 dB per S unit instead of 6, when compared to the dB markings on the meters!

I guess thy must use a complex external circuit to make meter sensitivity change at S-9 to a entirely new slope, to make up for the engineering mistake on the scales.

Collins also.

You can end feed a 'dipole' with ladder line through a balun and a
tuner.... Usually hung horizontal. This will give you a multiband
antenna from the dipole length and up in freq.
Unfortunately there is very little written about doing this. I have
only tried it once, portable, where I could not use a center fed
antenna. It did tune and seemed to work OK. I do not have a lot of
experience with it.
Worth trying ... it is simple, and a tuner / balun are ez to homebrew
and/or find used (check e-Bay, they always have caps, roller inductors
and commercial tuners for sale)

> bunch of connectors in the line or are doing precision measurements.

As I have found out that all "depends" on two factors. The first is the type of dielectric material used, and second the length of the connector. I did a simple purely mathematical study of a 1 inch long SO-239 barrel connector, with a PL-259 plug on each end, for an overall length of 1.25 inches, as a test case. I have always heard the rule of thumb not to use UHF connectors above the 2 meter band, and I wanted to find out why they are so "bad".

The data below was calculated based on the formulas I looked up to calculate the Z of a coaxial conductor system, and the loss less transmission line equation. All the calculations assume a pure load Z of 50 ohms connected to one end of the barrel connector. The barrel connector, and plugs, are treated as a transmission line with the length corrected for the frequency used.

For a Teflon dielectric with a dielectric constant of 2.1 I get:

Zconnector=34.5 ohms

440 MHz; SWR=1.365
146 MHz; SWR=1.112
52 MHz; SWR=1.039
29 MHz; SWR=1.021

For the cheap Penolic dielectric with a dielectric constant of 4 I get:

Zconnector=25 ohms

440 MHz; SWR=2.241
146 MHz; SWR=1.335
52 MHz; SWR=1.109
29 MHz; SWR=1.06

And for the record with an Air dielectric constant of 4 I get:

Zconnector=50 ohms (Hum, very interesting!)

This would strongly suggest a UHF connector using mostly air should work almost as well as a "constant Z" connector design. This would explain the rib structure used to hold the center conductor in place on the high quality SO-239 antenna mounts I have looked at, and the connectors on the back of some V/UHF SWR-Watt meters too.

As you can see either dielectric type will give acceptable results on the 2 meter band, and below, with a perfect 50 ohm load. However on the 70 cm band, unless you have a load close to 50 ohms, even the Teflon dielectric may not work well, while the Penolic dielectric material is out of the question. Both types of dielectric material appear to be OK for use on the 6 meter band and below. Remember that the above results are calculated for a "Z bump" of 1.25 inches, a much longer connector, such as the long bulkhead ones I have seen at Ham swaps, can cause SWR problems even at HF!

So like I said it all "depends", and using "N" connectors, or other "constant Z" connectors, may not be such a dumb thing do, even below 400 MHz.

IMHO I guess it pays to go back and reexamine rules-of-thumb. Its amazing what a little bit of investigation teaches one about how these rules-of-thumb come about, and how to apply them in an intelligent manner. Ham Radio, its a learning process for me as much as getting on the air and yacking with other operators.

The purpose of the SO239 connector is that if the antenna breaks, or fails for some reason, it is easy to disconnect it from the choke coil and reattach another. If you don't mind cutting and soldering coax, then you can save some money and attach the wires directly to the coax. Just remember to strain relieve everything. If you want pictures and ideas on any of this, go to the library and look in the ARRL handbooks, or look at AC6V's page on antennas to find all kinds of info.

I've never seen a Penolic dielectric barrel connector, but of course
there are a large variety of connectors manufactured.

Barrel connector could indeed be a problem at UHF, if long enogh and
if the construction is poor enough. The could be a problem at VHF, if
the same poor quality applies and you use enough of them in the line.

>And for the record with an Air dielectric constant of 4 I get:

A common trick, if you have a critical application, is to drill out
most of the dielectric in a standard connector. Pretty much needless
at lower frequencies, but in critical applications it can make a
difference at upper VHF and higher.

>ones I have seen at Ham swaps, can cause SWR problems even at HF!

I've never seen that, and I use plenty of bulkhead connectors. It
would take almost a foot long female connector to cause a problem at
ten meters, or a bunch of shorter bumps placed at stratigic spots in
the line. Even so, the effect on loss would be low.

By far the biggest worry is some connectors, like those from Radio
Shack, overheat at high power levels (over 1000 watts) during extended
transmissions.

>So like I said it all "depends", and using "N" connectors, or other
>"constant Z" connectors, may not be such a dumb thing do, even below 400
>MHz.

Anyone using N connectors in QRO applications is asking for trouble.
Especially if SWR might ever get high.

People are often too concerned about SWR, and not enough about
comnponent reliability. An SWR of 1.5:1, especially if it is induced
near the rig end of the feedline, is meaningless in most applications.
The exception would be if the rig shuts down from the SWR, or if the
impedance goes "high" and unloads a fixed-tuned PA.

I think the perception SWR must be perfect comes from misuse of the
term "mismatch loss", or a lack of understanding of what SWR means and
how it affects the system.

I can have pass current through a 1/2 wl of wire that delays phase 180 degrees, less than 180 degrees, or more than 180 degrees.

So you have to be careful how that "wire" is arranged.

As Roy pointed out, these small balanced stubs often radiate. Linear loading systemn do that.

Depending on which direction you fold the linear loading, you can move the load anywhere from out on the element to in on the element from the actual attachment point.

Hi Den,

That only works if the balun is imperfect, and in every case where the
antenna radiates the feedline will also radiate.

Any end-fed antenna needs some sort of "counterpoise" to push against,
if you don't give it one it will find one on it's own, and the results
can be undesirable.

OhOh, gotta be careful here. The voltage is what actually causes the current to flow into the finite impedance of the upper radiator. The problem could be stated:

1) What must the voltage (complex) be at the upper terminal of the phase inverter in order to induce the specified current (complex) flow into the upper element?

2) How can I design a phase inverter which supplies the necessary voltage _and_ current into the load (upper element)?

EZNEC could easily model the LC circuit embodiment, with and without
counterpoise.

>
> Nice point about the stub radiating! They sure do even when we hope
> they don't. The J-pole is an example of that.

In the Jpole, the stub is colinear with the radiator. The current on
the stub is of the opposite polarity to the current on the radiator and
will slightly reduce the broadside gain compared to a simple dipole.
Bending the stub so it is perpendicular to the radiator causes the
radiation induced by the stub to appear at high angles, which in the
usual VHF application is considered wasted power. The power may seem
wasted but at least isn't used to destructively interfere with the
radiation pattern in the desired direction. An even better approach is
to go ahead and balance the system with another radiator below the
(horizontal) stub......

> We sure have to be careful applying "circuit models" to antennas.

Indeed. But carefully done, the exercise can result in considerable
insight into how antennas and transmission lines actually work.

Thanks Roy, for modelling the antenna and confirming it works as it
worked, hi hi.

I could make my work with a tuned circuit, but only when I dangled a
1/4 wl wire from a center tap on the tuned circuit.

It also worked with a stub.

I suspect it wouldn't have worked at all if I folded the stub up.

Nice point about the stub radiating! They sure do even when we hope
they don't. The J-pole is an example of that.

We sure have to be careful applying "circuit models" to antennas.

Roy,

Well, I've measured my S meter's accuracy, and it is
exaqctly as Reg described. This was on a cheap
Uniden - the "President" model which also goes
by model number 2510. It is a 10 meter all mode
radio, used as the IF for a 6 meter transverter.
I measured it because the transverter seemed to
hear very poorly. Any way, it was exactly on,
yet the setup was still deaf. I got to questioning the
accuracy of my signal generator - an HP 608 D.
So I brought the setup to a friends house, and he
measured it with his test equipment - it was spot on.
But there was a major difference - when we hooked
the transverter to his antenna, all of a sudden I could
hear 6 meter signals. 6 antennas later, I'm still
fairly deaf at my qth - but the rig works.

My guess is that most new radios are fairly accurate -
when the s-meter shows S-9 you've got close to
100 microvolts. I expect accuracy drops off the farther
away from S-9 you get. My Uniden was pretty good
down to S 3 or S 4 - I don't remember which.
When I get a few projects out of the way, I'll drag
my 746 over to the generator and see how accurate
it's " s-meter " is. (Not a meter at all - a horizontal
bar graph on the LCD display). The same ham who
performed the second test on my Uniden - he also
uses an HP 608 D - tested his 756 and found it was
slightly off in the wattmeter. I do not remember whether
he tested the S meter, but my bet is he did. He is quite
meticulous about those things. If he did test it, he would
surely have told me if the S-meter was off. I'll have to ask
him. Or, if you work him, you can ask him yourself.
His call is WA2WEJ

I find it amusing, not that it makes any difference for antennas, that since the meter is no longer defined by the length of a metal rod in Paris, it is now a derived unit with c in meters per second the conversion factor from light-seconds to meters,
1 light second = 299792458 meter
or
c = 299792458 meter/second
exactly. This is similar to other standard conversion factors like
1 inch = 2.54 centimeters
exactly.

It also means that the SI conversion factors epsilon_0 and mu_0 are also given exactly: mu_0 = 4 pi 10^(-7), and epsilon_0 = 1/(mu_0 c^2).

Maybe if the French revolution had occured in 1989 rather than 1789, we would have a metric system with the length unit equal to a light second and c would have the value of 1 in those units.

I know about "N" connectors, I have a few, and have installed them on some LMR-400 cable. But, I am looking to upgrade a system without having to switch everything over to "N" connectors, and the type of UHF connectors I am looking for should perform almost as well as the "N" connectors at UHF. That is if I can find any.

As far as the "N" connectors being cheap the best price I have found is around $3 to $4 USD each for the male clamp type, at local Ham swaps. I don't like the cheap solder "N" type connectors, had to get the metal too hot to solder which started to melt the jacket on the ultrafelx LMR cable I have.

My reading of the claims (a literal reading, like a lawyer, since I
don't know enough about the topic to understand the implications)
is that it patents the placing of a conductive element of some sort,
either grounded or parasitic, close to a fractal antenna for the sole
purpose of changing the resonant frequency and/or bandwidth of the
original antenna. It seems to me this isn't very general. It doesn't
prevent you from just designing the original fractal antenna for the
desired resonant frequency and bandwidth, nor does it seem to prevent
you from adding elements to the antenna to change other parameters,
like gain or directivity (though I guess it might take a trip to court
to show that you added the elements solely to increase gain or directivity
and not to change the resonant frequency or bandwidth).

This seems to be quite a narrow patent. The description in fact
goes through a lot of material which doesn't seem to be covered in the
claims. In the field that I work in this is generally considered
bad practice, since it reveals stuff that you aren't patenting, but
it may be that other patents that cover some of this are forthcoming
or, perhaps, that he wanted to make sure no one else could patent
the material if he couldn't.

This is a continuation of two predecessor patents, now abandoned.
This sometimes, but not always, indicates that the patent examiner
rejected the meaningful claims in the earlier applications. If so
this can result in a bunch of narrow patents being split off so you can
avoid delaying them while you argue about (or give up on) the
contentious issues.

I don't think this patent constrains the field for fractal antenna
builders very much, though people may need to design their own to
ensure that elements for the purpose of changing resonant frequency
or bandwidth aren't slipped in. Maybe the good stuff is yet to
come.

I hope that the following information will prove useful to you. There has been quite a bit of misinformation given mainly because of the perception that were going to use 200 watts on CB. You did not say that was your intent.

Find some 14g (16g is probably fine too) or better wire, around 19 feet worth should do. There are ideal types of wire for this purpose such as the copper clad type, but even speaker wire works very well and will last a long time. As someone else mentioned you will also need a panel mount SO239 connector. Some UV resistant rope, electrical tape and some silicone round up the rest of the materials needed. You will also need another part which works with the antenna, some RG58 cable with the proper terminations ie PL259.

Cut two pieces of wire to 8'10" long or more. Solder the end on one to the bolt hole of the panel flange on the SO239 after making sure it is looped though and twisted tightly. Solder the second wire to the centre of the SO239. Now silicone each joint to make it water tight. I should mention that the silicone is best if is not an acid cure type. Take some rope and tie it to the flange wire about one inch from the joint and the same on the centre wire. The idea here is to strain relieve the joints such that the rope is tight before the joints get pulled on. You should now have an assembly of around 17' or a little more. More is better for now.

The next detail is important as it will help reduce currents on the outside of the feed coax. The RG58 coax should have 6 - 10 turns in a coil about 6" ID near one end, then end you will connect to your antenna. You can also use RG8, but it is more expensive and harder to work with for this. Tape up the coil with electrical tape and connect it to the SO239 on your antenna and then tape up the connector after making sure it is very tight to keep out water. How much coax is left after the coil is up to you as this is where you will connect your feed coax.

Now make an eye on each end of your antenna. These are not the final eyes so just make sure they are good enough to hold things temporarily. Don't worry about the length too much but the over length should be close to 17'. I don't know how you intend to support this, but keep it away from any metal objects by at least 20'. You could hang this in a tree. Anyway attach the support rope through the eye on the centre wire and haul it up to the operating height. Make sure that you have some method of keeping it straight like a bungy cord to something below, or a sand bag etc.... Also make sure that the feed coax and choke coil point straight out at right angles or as close to possible for as far as you can manage. Connect to your SWR meter and radio.

I am assuming that you know how to use an SWR meter. If you do not, then read up. Starting at the bottom frequency of interest and working up the highest frequency of interest, make note of each SWR reading. If the SWR minimum is not within your band, then you will probably need to trim. If the SWR keeps falling as you go up in frequency them go outside, shorten both ends by an inch and retest. If the SWR starts lower and keeps rising, then lengthen each end and retest. Hopefully there is enough extra wires in the eyes to do this. Once a test run show the SWR reaching a minimum in the band the next step is easier.

Divide the frequency of SWR minimum by the desired centre frequency band of interest and multiply the result by the existing length of the antenna to find the correct length needed. Go out and make the "final" adjustment to match this length. Check your SWR one last time of course to make sure.

And there you have it. A simple dipole. Maybe not the best dipole, maybe not the most efficient antenna, but you made it. There are many other aspects of antenna installation that I will not go into here like safety and grounding, but the library should be of great use here and I recommend that you do some real research into these other aspects before installing any antenna. I don't want to be responsible for any more accidents. None of the above is new stuff, just a rehash of many articles and instructions from the past. Have fun and don't worry about perfection too much.

: How about remote mounting the antenna for the field strength meter outside
: and monitoring it from the shack?

That could be done. The Bird wattmeter has the capability of remote
location of the sensor section. But you need a conversion chart to
figure out the SWR.

I have never worried about the actual ratio - just tuned for minimum
reflected power at the frequency where I wanted the antenna to be resonant.
This assumes that the antenna will be 50 ohms when the SWR is lowest, not
necessarily a proper assumption. But it is a quick and dirty method that
produces at least acceptable results.

If I want maximum performance, I just use a field strength meter and
don't even bother with the SWR meter.

Andrew, first the insulators ARE available at Home Depot, get a few feet of PVC about 1.5-2" stuff, cut in 4 or so inch lengths, drill holes ...voila!! Insulators, BUT if your wire is good stuff and well covered in insulation, it probably wont matter much, maybe a bit on rainey days (dunno, we havent had any in years here in Odessa.)
My full wave 80 meter loop is in the trees , literally, up at about 25 feet..Hey thats a big tree in odessa...it works fantastically on 80 and 17, plus resonably well on most any. It is feed directly with coax nothing but a coax wound 1to1 "collins balun" too keep rf off the coax...Its resonant at 3.922, where you can ususally hear me on Sunday nites after 8 central, as backup on the Continental Traders net...Join us if you can...more height is BETTER....but dont pass it cause you cant get it WAY up there...73 Murray

When it come to ground, especially on a mobile antenna, just remember one thing.....MORE IS BETTER .. That covers it,...chicken wire or fence wire is just as good as metal sheets and you can roll up a good 20 ft section and put it in a closet...be sure to also attach it(the ground wire) to any rails, gutters or what else...good luck ....Murray

I found your experience really interesting, because I've used the acetic acid stuff for decades on all sorts of material, including copper, aluminum, and copper, and never seen any corrosion at all, even after years of encapsulation. Barry Ornitz, I believe it was, pointed out that RTV formulations vary widely, so apparently some are ok and some not. In the U.S. you can get GE Silicone II, which doesn't smell like acetic acid, at home handyman stores. I've found that it can take much longer to cure, though, and sometimes it seems to never cure. Of course, there are numerous industrial formulations if you want to go that route.

If you add capacitance hats, it'll reduce the amount of inductance you need, will raise the feedpoint resistance some, and will make the antenna less narrowband. That is, they'll act a lot like you're just lengthening the antenna. The tradeoff is, of course, increased mechanical complexity. There won't be any significant improvement in performance in your case except a bit broader bandedness.

Source record: 182324

"Dan K Nelson" <w6dkn@qsl.net>
shared these priceless pearls of wisdom:

->
->RG-58 has about 5 db loss per 100 foot at 150 mhz. Even a 50 foot run will
->result in a loss of about half of the power fed into it, as well as half of
->the received signal strength. I would think that a 25 watt marine radio on
->the open waters would opt for max range and reliability, therefore he would
->probably want to use an LMR-400 or 9913 type cable to keep feedline losses
->at a minimum. If so, a UHF or type N connector would be appropriate.

Y'all ever actually DONE one of these installations before, sir, or spent a
dozen or so years in the industry?

When you have, please offer your "think" as opposed to standard practice.

Hi Tom,
Yup, I know this is MUCH less than ideal.... when in a pinch try
anything... Is feed line radiation bad in a marginal set up? Probably
not so long as it isn't in the shack! Hell, there are times I'd wish
for radiation from anything...

I am just passing along one of the ARRL designs that I have tried and
made Qs on. I was stuck 'end feeding' my ladder line multiband because
of the real estate I had to work with.. Jumped the centers together and
moved the ladder to the end... it did seem to tune and radiate, but
then wet noodles make Qs on a good day. Hee Hee

Hi Mike,
I'll leave the techie stuff, what will or will not properly measure the SWR, to the techies.... beyond my knowledge.
From experience:
You can increase the sensitivity of a bridge type SWR meter by adding a simple 1 transister DC amp to the meter. This was commonly used in QRP work and was published for years in the ARRL Handbooks. If I remember correctly it was an NPN xister driven with a 9 v battery.
If you e-mail me @ dspiess.idt.net I will look up the exact circuit at home and give it to you.
I have added this amp to a Radio Shack SWR bridge and used it with an HW-8 an 2 watts or so and had lots of meter gain to spare.
An op amp might work too, but I have not seen an actual circuit using one.

Source record: 182372

Hi Roy--

The AD8307 provides RSSI over a 90-dB dynamic ranage with 1-2 dB accuracy, and up to 120-dB range with a front end. At over $6.00 a pop, though, I don't see rec.radio manufacturers lining up to buy them. By amateur equipment standards, that's a very expensive part.

Accurate S-meters do exist, but mostly on commercial radios. For example, the Ten-Tec RX340 meter covers a 120-dB range and is calibrated in both dBm and S-Units. According to the HP-8640B, it's dead on over most of that range--and compensates when the attenuator or preamp are switched in (no change in reading)

Of course, the psychological effect is boring, as you suggested. 120 dB is a huge dynamic range and the meter movement doesn't flap around much--ruining its entertainment value. Also, the scale resolution isn't very good for really critical readings (the scale's accurate, but marked in 5-dB increments)..

In fact, it's possible to more accurate on-air comparisons by using a step attenuator and referencing signals to a single point in the least-accurate range of a conventional S-meter meter (that part where where a 2-3 dB change equals a lot of motion--usually between S2 and S8 before the response really begins to compress).

I've found the "sample and hold" hang function on some of the newer rigs is especially useful for comparing SSB signals.

If you need only 60-70 dB dynamic range, you can build a tunable field-strength meter using one of the cheapo FM ICs and use the RSSI output. Those tend to be very accurate. Filter it well at the IF and it will only see the specific signal you want to look at in a crowded field. Ignore the FM limiter section and detect off the RSSI line. You can even add it as a parrallel IF strip in an existing receiver (as long as there's no AGC ahead of the mixer and you keep the BFO signal out of it's IF).

An attorney here advised that "The CC&R's are encumbent on the property whether you signed them or not."
In either case your rights to install an antenna have been waived if the CC&R's so state.
Really this is not a matter of right or wrong in an emotional, common sense judgement. Freedom of speech, valid FCC license etc. It is a matter of what is the legal judgement and more times than not -- the legal system sides with the CC&R's.

Note however that in CA some HOA's have given in and allowed small TV dishes -- a CA law entered the scene. However other HOA's are not allowing them, pending court action or an arbitration board.

For some web pages regarding all this -- see URL:
http://ac6v.com/page9.html#CC&R

Read the CC&R's carefully -- one here in San Diego states "There will be no Shortwave Operations in the complex"
Gee -- scrap you cell phones and cordless phones huh!!

Bottom line -- don't buy a home with CC&R's!!!!

Excellent comments, Roy. There's more - I'm aware of one instance where the buyer took his own attorney to the closing. The attorney informed the gathering that the buyer was not going to pay some of the fees commonly paid by the buyer in the closing process. There was a bit of a delay as the details were discussed and paperwork changed. The result was the buyer saved enough to pay his attorney for the session, and buy a nice antenna with the remainder.

Hi Bart,
the reason I was interested in the behavior of overcoupled
resonators vis a vis collinear antennas is that, if one could
consider each element of such an antenna as a simple harmonic
resonator coupled either by an electric field or a capacitor,
one could come up with a very elegant and simple explanation as

to why Tom Rauch's split inductor coupler worked, while coupling with only a lumped element tank circuit was problematical. I realize this is a stretch, but it's intriguing, nonetheless.

Using the coupled resonator approach I can envision problems with the double bazooka antenna because of the inevitable phase shifts and concomitant change in pattern, but, you're right, that's the subject of another thread.

Has there been any cogent explanation of the claims? Obviously there won't (can't) be any significant critique but I wonder if he's making any attempt to actually describe (as a teacher) what the patent is all about. I would be particularly interested in his explanation of how Krauss et all managed to botch the theory of small loops.

Of course that would be helpful.

The ad boys at National, during the early fifties, bragged about their "lively
S-meters"
As I recall on an NC125 most signals were between S8 and full scale. Certainly was
a pleasure giving out signal reports w/o having to appologize for having a
"scotch" meter :) !

The basic operation of the system is achieved if the phase inverter is considered to be a center tapped autotransformer. The center tap is grounded and the other two ends connected in the radiating elements. The rub is that the magnetizing impedance of the transformer needs to be 10,000 ohms or greater. Virtually impossible at MF and HF without resorting to some sort of resonant circuit like a tank or stub.

Choice of the L/C ratio, or differential mode characteristic impedance of the transmission line stub, results from carefully trading off several performance parameters such as system bandwidth, broadside gain and sensitivity to geometric and environmental changes. As far as I know, optimized systems always turn out to be overcoupled and exhibit multiple resonances _outside_ of the useful system bandwidth. Remember, every 'hump' in the system response is associated with a phase shift of up to 180 degrees. For the collinear to be successful, the phase relationships need to be maintained within 60 degrees or less. Therefore, the useful bandwidth for collinear operation will be less than the bandwidth of any single resonance peak.

> Using the coupled resonator approach I can envision problems with the
> double bazooka antenna because of the inevitable phase shifts and
> concomitant change in pattern, but, you're right, that's the subject of
> another thread.

I think it's the other way around. The phase shifts associated with the multiple resonances are what limit the bandwidth of the collinear antenna. The whole point of adding the resonator in the bazooka is to introduce an additional frequency dependent reactance (loosely speaking, phase shift) which compensates the frequency dependent phase shift inherent in the center fed dipole antenna. The objective is to widen the _amplitude_ bandwidth of the complete system. Since there is only one radiating element in the system, there is no relative phase to

control or possibility of pattern distortion. Unfortunatly, the Bazooka doesn't really work as intended in practical amateur implementations for 75/80 m where broadbanding is most needed. The technique is integral to the broadbanding schemes used in many modern systems of high complexity such as multiband curtain arrays.

Switching in extra filters that match the passband of the filters in
my receivers just so I can use a meter I have to re-scale doesn't
sound like a fun project.

I think a better solution is, while rescaling the meter, to just make
it match the slope of the receiver AGC.

Better yet, I just won't worry about having one of the 3 good S
meters in the world.

An article I wrote for the LOWDOWN describes a simple LF antenna analyzer. The analyzer itself does not measure SWR, but the article contains a schematic and discussion of the type of resistive SWR bridge shown in the ARRL Antenna Book, and also discusses how to make it work for impedances other than 50 ohms. It's available in the File Libraries section of the LWCA web site at

Recently I set out to build a "rotatable dipole" for 20 meters. It seemed the best way to get coverage in all directions as well as realize a slight amount of gain and some directivity. The first problem was that I did not have the turning radius for a full size antenna so I used a program I got off the web somewhere (lost the url) called "reducer" which gave me the data I needed to reduce the antenna length by using loading coils. The antenna is about 60% in size, right at about 20 feet long and the coils are 1 and a half inches in diameter with 22 and a half turns each for a load inductance of 6.59 uh. All of this is per the calculations of the reduction program. The problem is the antenna will not match! I cannot get any reasonable SWR reading or the thing to take any power at all. No amount of pruning or lengthening accomplishes anything. I have always been able to get dipoles to take power before just by simple pruning. I am not a novice at building antennas but this is my first experience with loading coils. Am I missing something? Perhaps I need some type of matching circuit at the feedpoint...the reducer did not specify this though. Any of you antenna whiz kids out there got any ideas? I am completetely frustrated. By the way I did check the coax for shorts and open conductors so that is ruled out.
Thanks for any help...

We have pretty wimpy thunderstorms here in Seattle, but I have seen arcing in my equipment before. Before I moved into my condo, I lived with my parents and had dipoles, beams, verticals and lots of wire on our roof with about 4 feedlines into my bedroom. I would wake up at night during a thunderstorm counting the seconds between the thunder and the flash and run out of the room when it got close! More than once I have seen (and heard) electricity arcing in my antenna tuner. I always had my radios unplugged though. I am sure I even saw an arc between the center conductor and the ground shield of a coax cable once that was unplugged. Even when the lightning was a couple miles away I would hear a snap as it flashed outside. Pretty creepy!

Hello, CW,

Gee, how did you set up your kill file? Several months back I set up a kill file for "Frac", "fractal", "Chip", "N1IR", etc., etc., and nowadays that doesn't even come close to getting rid of all the garbage. The threads are too varied and too insidious now to handle with a simple kill file. I long for the old days when this was a really great newsgroup.

In July, I was off for a couple of weeks or so because of work and when I got around to checking the newsgroup again, out of 1850 unread messages some 59% were of the bickering, abusive kind (you know the type) going to or from fractenna (I actually counted them). Can you believe that? At one point in July, 2000, there were eight, separate, endless, simultaneous threads on the matter. For most of the month, there were at least six. Unbelieveable. It's been like this since almost the beginning of the year.

I used to get a lot out of this newsgroup. It's not nearly as useful and educational to me as it once was, because I think people who have something to say are simply getting crowded out. It's like trying to get a word in edgewise with a gasbag at a party. I can't believe we have to put up with this, but, after all, I guess there is a First Amendment.

I also realize I've just added to the problem, but if I were face-to-face with you I'd still say what I just said. As Mr. Sabin sometimes says, I'm not interested in any replies to this post and I don't wish to further my comments on this subject. Please don't bother replying to my rhetorical question.

Disgustedly,

Al W6LX

Something I should mention, that was pointed out to me via email...

When I mentioned that I wanted to build the dipole to be able to handle 200 watts, I didn't mean I was going to run 200 watts on CB. My Cobra 2000 only puts out 18 watts PEP on sideband, and 4 swing 16 PEP on AM. RMS the numbers are much lower (4 to about 7 or 8 on AM).

I'm overbuilding the antenna because I am studying to get my ticket. When I do, and I'm hoping to go straight to General class, I was hoping to modify the antenna to transmit well on 10 meters for that very purpose. On 10 meters, I may run up to 200 watts. But not until I have my ticket. I have an old tube amp that my stepfather passed down to me. It's not hooked up. It's waiting for the day that I do get my ticket.

I hope I didn't offend anyone, or put anyone off with this misconception

Source record: 182397

This antenna will be quite narrowbanded, so you'll have to get the loading inductance pretty close to see any resonance within the band. The amount of inductance depends strongly on the dipole's diameter, and much less on the antenna's height. According to EZNEC, you need about 5 uH total, or about 2.5 uH per side for a 1" diameter antenna, and 7.8 uH total for a dipole made from #12 wire. When resonant, the feedpoint impedance should be about 23 ohms plus coil loss for either diameter, so you should see about 2:1 SWR when you get the loading right. If you want better than that, you'll have to use some sort of matching arrangement, but most rigs won't complain about 2:1. If you don't have an antenna analyzer, dip meter, noise bridge, or other way to find resonance, I'd temporarily add some inductance, then tap down on the coils until you find resonance, then make a more permanent connection after you know about the right coil size. The antenna will be more narrowbanded than a full size dipole, but otherwise just as good for all practical purposes (if you can keep the coils clean and dry).

I bought some that appeared to have a teflon dielectric and silver plating,
The first time I tried to solder the center connector it "unrolled" into a
"U" shape instead of remaining a tube. I also had a devil of a time getting
solder to stick to it.

I've also run into the ones with the brown dielectric and that stuff starts
melting when you are working on the braid, let alone the center connector.

If either of those were Amphenol then they have come out with something less
than their usual quality. <:-))

I reply:

1) Construction is extremely difficult, much moreso than other verticals. This is due to ambiguous instructions.

2) It does tune very easily.

3) I've had very good luck, performance wise with it on my roof.

4) It has a tremendous problem with RF feedback into the shack. You must RF-ground this antenna by using a RadioWorks 4K Line Isolator unit in between the transciever or linear and the antenna tuner. You must have a very short grounding braid connected to two or three 8 foot grounding rods very close to the shack to eliminate the RF feedback.

5) I'd use this antenna with an EXTERNAL antenna tuner. An external antenna tuner has the desirable side effect of not letting the antenna "see" the spurious resonances put out by your transceiver.

6) I think that an antenna with radials such as the Butternut or Hustler will give you lots better performance and fewer hassles in the long run.

Hi Tom,

One problem I see with slinky antennas is the effect of all that inductance is ignored.

For example slinky's are often used as Beverages, but the promoters assume the impedance of the slinky is the same as a non-coiled conductor and ignore the loading and phase delays effects of all the hundreds of turns of wire.

How many turns are in the slinky antenna you have? How are they distributed, evenly? How is the antenna fed, like a dipole? How is the feedline routed? How far from house wiring is it?

Remember any antenna right in the middle of your house is going to be a problem, becuase it will couple to every conductor within a few wavelengths with an intense field. I'd expect RFI unless you run flea power.

Can you get anything outside? No balcony?

A question re 'N' versus PL-259 connectors; based on information posted here.

So 'N' connectors may be a problem at high powers?

Reason I ask is that I was thinking about using 'N' type at base of my sailboat mast for marine VHF (max 25 watts) because it looked a lot more waterproof than the PL-259/SO-239 type. Whatever type I'll probably put it in a heat shrink sleeve anyway.

Any advice would be appreciated.

N connectors are fine at power levels below a kilowatt. They are, if
properly installed more water resistant than UHF fitting assuming both
are exposed to water through lack of external protection.

If you heatshrink connectors, use flooded heatshrink to seal the
connection. Otherwise you are better off with tape and a sealing
compound like "vapor wrap".

The only thing worse than not sealing a connection at all is....
sealing it so water leaks in and can't get out. As a matter of fact,
I'd use flooded cable in any marine installation along with flooded
heatshrink.

Terry Sanford <tsanford@roadrunner.nf.net>
shared these priceless pearls of wisdom:

-
->Reason I ask is that I was thinking about using 'N' type at base of my
sailboat
->mast for marine VHF (max 25 watts) because it looked a lot more waterproof
than
->the PL-259/SO-239 type.

N is way, way overkill. BNC is smaller, lighter, a hell of a lot easier to put together, and comes in the right size for RG-58 cable, which is probably what you will want to use at 150 MHz. and 25 watts.

If you want it REALLY, REALLY waterproof, squeeze some silicone seal onto the connector, then shrink sleeve over that. Make sure that you shrink it from the center out to the edges and that some silicone "bleeds" out the end of the sleeving where it goes over the coax. It will take a knife and an afternoon to ever get it apart again, but it is guaranteed waterproof for life.

RG-58 has about 5 db loss per 100 foot at 150 mhz. Even a 50 foot run will result in a loss of about half of the power fed into it, as well as half of the received signal strength. I would think that a 25 watt marine radio on the open waters would opt for max range and reliability, therefore he would probably want to use an LMR-400 or 9913 type cable to keep feedline losses at a minimum. If so, a UHF or type N connector would be appropriate.

Just a guess here, but it's worked for me on a mobile. You might try moving the loading coils to the ends of the dipole instead of the center. At least that way the coils won't interfere with each other as much. you might even be able to match it up.

Source record: 182411

Andrew,
Horizontal loops do work. They have draw-backs like any antenna does, but they do work well. One of the "pro's" is that they seem slightly 'quieter' than a random wire, or dipole antenna. The 'flip-side' of this is that the signal strength of all signals is 'down' from other type antennas. This also means that the signal to noise ratio is better. So, it's a trade-off. (I'm keeping my loop, by the way)
It would be nice if all suspension points used insulators, but, insulators are not really necessary even if the wire isn't insulated. You will get some reactance from not using insulators, but depending on how you feed the loop, those can be 'taken care of'. Not using insulators also means that you will eventually 'rub' the wire in two. Guess that depends on the wind and weather in your area.
If you've got the choice, go for altitude! Inclose the largest area inside the loop as possible, the more the better. That means that a circle shaped loop is 'best', a triangular shaped one is almost the 'worst'. A very long, narrow loop IS the 'worst' shape (folded dipole).
As long as your only receiving with it, I'd feed it with ladder-line and forget about the mismatch. One trick, if you do it that way, is that you can turn the loop into a 'long wire' by disconnecting the ground 'side' from the receiver. That changes reception for the 'better' some times (and sometimes not). When you get HF privileges, and if you want to use the loop for transmitting, feed it through a balanced tuner. Depending on the tuner. you can use it almost any-where, even two meters.

Michael,
The other posts have good ideas so I'd try them. I just
wanted to point out that while you will get some directivity
from using a rotatable dipole you will get no gain. in fact,
with the 'shortened' rotatable dipole, you'll probably loose
a bit. That's not necessarily bad, 'cuz you do get some
advantage by turning it.

Source record: 182414

Hi Andrew,
I use a 40 meter full wave horizontal loop at 20 feet. The antenna is fed with 450 ohm transmitting style twin lead through a Johnson KW Matchbox. The antenna is very effective. With 200 watts on SSB on 40 in six months I worked WAC. This was going through the sun spot minimum. The antenna picks up less noise than a dipole at the same location. I use the antenna on all bands except 160 meters.

I use UV proof rope at the four corners as insulators in a flag pole style pulley system. Use the insulated wire and you can pull the wire through trees with very little degradation. My supports at the four corners are TV antenna support masts (two at each corner). I recomment the use of the twin lead feed with at minimum an antenna tuner that uses a balun to balance the tuner output. I do not recommend the use of coax cable to feed the antenna for transmitting. Coax could be used for receiving. Use with an antenna tuner and balun for best results.

Disconnect the antenna from the receiver and ground it unless you are using the antenna. This will help to reduce the possibility of lightning damage to the radio equipment. The loop should cover as large an area as practical and it is not necessary to have a square antenna set up. I feed my antenna 1/2 way down one side. I have no interference to any electronic equipment in the house even at the 1200 watt level. The antenna is 15 feet from the house and telephone system.

I infrequently serve as net control for the West Coast swap net using this antenna and am told it is very effective.

Good luck in getting on HF. It can be very enjoyable.

Um, Art... A killfile is done on the receive end, kindof like squelch. You might be in someone's killfile, but that doesn't mean you can't post.

Roger, et al-
Do you really mean "Acetone" (dimethyl Ketone) or do you mean "Acetic acid" (smells like vinegar)?
There is a world of difference, and it IS important.
Acetone is a solvent, used in lacquer and various paints, and in Nail polish remover. Sometimes used to thin Epoxy.
Acetic acid is one of the common acids. At 5% solution, it is sold as vinegar- in The common Silicone caulks, it is released by reaction with atmospheric moisture, to initiate the curing process.

>Amphenol rates their type-N at 1500 Volts, peak, and their type-UHF at
>500 Volts, peak.
>No mention of power handling in the catalog.
>Regards, Jim

Hi Jim,

I have no idea where or how those ratings were derived, but a
PL259/SO239 combo will handle a large amount more voltage and current
compared to a N. The N is dimensionally almost identical to a BNC as
far as conductor size and air gap in the connector.

I typically highpot all my jumpers before installing them, and just
last week highpotted a harness with N's and UHF fittings at opposite
ends. The N's were the voltage limiting connector, arcing between the
pin and the ground around the pin.

If you take the bayonet off a BNC male, it makes a dandy N-type quick
connect for the test bench.

>dielectric. These are a problem at high power levels?

The ones I am thinking of have a brownish plastic dielectric. They
swell up and stink at 1500 watts or less on RTTY or extended time on
CW.

>I remember a thread, on this NG, some months back about how much power a "N"
>connector can handle. I don't recall anyone ever finding a spec for a given
>manufacture's connector.

Into matched loads at HF, you'd be amazed at what cable and connector
can take what power. But any N has always been the weak link in my
systems. I take N females on my 7/8 Heliax and bore out the center and
shorten it. I add a center pin from a SO-239 with polyethelyne tubing
or PTFE tubing over the pin as an insulating sleeve. That gets rid of
the weak spots in case I accidentally hit the wrong antenna on the
wrong band at full power.

If I leave an N in line, it becomes toast. Generally on the furthest, highest, hardest to reach connector in the middle of the rainy night during a contest.

The first thing I'd do Tom is re-mark the scales on the meters, so the
scale was divided so that 6dB with a given current change in the meter
above S-9 was the same as an S unit below S-9.

Then I'd build a separate receiver for the S meter using a log amp of
some form with a step attenuator, and keep it out of the AGC loop.

Hmmm. Sound's like too much work to have the S meter. I'd buy a W-J
commercial receiver, make sure it was correct, and give dB reports
over my noise floor.

As was pointed out, S-9 on my antennas might be 10 dB or more
different than S-9 down the road. So who cares?

Jack,

I can add a few comments to those already posted. When I began my search for a home here in Dallas, I found a realtor who was also a ham. He was very aware of what I was looking for. Once I found a property I was interested in, his friends at the title company would get us copies of the deed restrictions. Another local ham is a lawyer and reviewed the documents as well as the city zoning at no cost! I also spend some time at the city planning office talking to the zoning people and building inspectors. Before I closed I was able to get the documents together for a permit and get it to the city.

While I chose not to have a contract that was contingent on getting a permit from the city, that is an option to discuss with your agent. Always do the research yourself and have the documents reviewed by an lawyer.

I wound up with a nice older home (1978--still some restrictions, but none related to towers and antennas...mostly size and design) and a permit for a 60 foot tower with a 2 element 40 meter beam and a triband yagi.

Well, it seems to me that it doesn't matter in any
event. My S meter reading is only relevant to
comparisons I make at my station. You could
be putting a tremendous signal into my area.
A ham 1 mile away might see your signal at
S 9 +40 if he borrowed my rig. Then drag
my rig back to my station and the signal might
be S6. Same S meter, same source, but 2
different locations with two different antennas.
So whether my S meter is calibrated or not
does not seem all that important. But I would
like the delta to represent some precise figure.
It would be helpful to know exectly how
many db's difference there was between
antennas, or for F/B or F/side measurements.
Actually, I'd like that in digital readout.

And I'm surprised that both you and Tom
don't get 6db per s unit - so much so that
I intend to repeat my test. I trust you guys
enough where it makes me suspect my own
measurements.

Roy Lewallen wrote:

In context, your statement is correct, no problem.
But, if taken out of context, (and this "wrong way
pruning" is so often a problem that that is likely)
your statement is both wrong and right. The
problem is that it does not include a reference
to the design frequency.

There's a neat "graphical" technique to eliminate the
confusion.

Take an 8 1/2 by 11 piece of note paper.
Draw a smile on it, the full width of the paper.
Label the left end of the smile with two
labels: "lower frequency" and "longer".
Label the right end of the smile with
"higher frequency" and "shorter"
Lable the center of the smile with
"lowest SWR" and "design frequency".
Then take 3 swr readings - one below,
one at, and one above the design frequency.
If they are increasing in value, they correspond
to the slope of the smile from the center toward
the right side. That tells you your antenna is
shorter than it should be. If the readings are
decreasing in value, they correspond to the
slope of the smile from the left hand toward
the center. That tells you your antenna is longer
than it should be. And if the lower frequency
swr reading and the higher frequency swr reading
are both higher than the swr reading at the design
frequency, the antenna length is just about right.
At that point, you need to narrow down the
range of frequency excursion from the design
frequency, to ensure that it - the design frequency
swr reading, is at a minimum.

One of the inherent problems of looking at deeds is that often the deed is part of a parcel, which part of a section, and the section contains the restrictions in question even if there is no HOA. Usually you need someone really experienced with real estate to find the snake in the grass for CC&Rs, and as you state, that can cost money. However it should be noted that few people with competent lawyers buy real estate with flaws, but most CC&Rs don't cause problems for most folks. Hams probably are better off looking in older communities and SOME big cities or places outside any builder's plans i.e. you buy the land, and it's undeveloped then you hire the builder or some place built like that. Most places however are now the result of developments, and the best we can hope for is pre-emption either by the FCC or state legislatures (lots of luck, builders have well paid folks to lobby for them).

Source record: 182222

David,
I am familiar with that type of feed after I did
some work which I consequently obtained a patent
What I found that was interesting was to close couple
a short dipole, split in the middle and fed delta fashion.
varying the spacing of coupling plus also varying the coupling lengths,
provided multiple resonances (a multi point resonant
antenna or multibander)and also can be used as a matching system
I also did some work using a 'U' shaped element so that the
driven element could nestle inside the coupled element.
I would also point out that like the Fractal antenna, it did not
excite the imagination of anybody on this particular group
and I have quietly let it die and moved on to examine methods
of removing nulls in the forward portion of high gain antennas,
i.e. using a an extra reflector to cancel the two forward
nulls formed by a director
Again like the other patent and the Fractal patent this also
failed to capture the interest of the many experienced experts
of this group
However I am so deep in this particular experimentation I am
continuing so I can tie up the loose ends in my report book
before I move on to find something more beneficial to explore
that would interest and provoke discussion with my fellow hams
on this group..
With respect to the coax matching that you mentioned, by
lying inside the driven element brought me to think that the
cross over point of energy from the feed occurred at the
best matching point between the feed and the excited dipole.
This scenario lead me to believe that energy movement
between equivalent capacitor plates occured over a portion
of the meshed plates and not the whole plate area..
This also went over like a wet balloon with the experienced
people of this group so I dropped that idea also.
Of course all of this experimentation is because of the
'fun of the chase' or 'the hunt' as part of the hobby and not to
assume that you are a antenna expert which is the point
where unpleasant things happen..... but I digress...
Regards
Art Unwin KB9MZ

463. Simple homebrewed loop antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: jason_hsu@my-deja.com
Message-ID: <8nmkaeagq1@nnrp1.deja.com>
Source record: 182223
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.antenna

Has anyone here homebrewed a SIMPLE loop antenna? I have read a few articles on the ARRL site on loop antenna projects. The loop antennas seem to offer decent performance for an apartment, and the fact that loop antennas are balanced eliminates the need for an RF ground.

I should note that I don't want to buy a soldering iron (due to the fact it is a fire hazard and I don't have a workshop), drill, hacksaw, or other dangerous equipment. Also, I have NO experience in homebrewing amateur radio equipment. Can I build a loop antenna using just simple tools like a screwdriver, hammer, and socket wrenches?

N0UU

in reply to:

Date: Sat, 12 Aug 2000 11:09:21 -0700
From: Roy Lewallen <w7el@eznec.com>
Subject: A collinear conundrum

I'm bothered by the statements that a resonant parallel tuned circuit is

different than an insulator "because of the circulating current". IF the

parallel tuned circuit is lossless, and IF it's exactly resonant, and IF

you're considering its steady state operation at only one frequency, the

resonant parallel tuned circuit is indistinguishable from an insulator. It will be different under transient conditions, that is, when power is first applied and the stored energy is building up or when power is removed and the stored energy is released. But in steady state at one frequency, a resonant parallel tuned circuit will behave exactly like an

insulator.

471. Antenna Restrictions and Covenants

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: stoskopf@tri.NET
Message-ID: <399EE2F0.38B97D2C@tri.net>
Source record: 182231

I've thrown this out before, but new people asking:

My present and hopefully final QTH had such CCRs. I bought the first lot and insisted before closing that I get a letter from the homeowners assn (then only the builder) allowing my antenna (65ft tower with antennas on top). Got the letter, filed it with the deed. Later purchasers protested, but it is a done deal.

Other way to do it is to get ALL of the owners in the assn to sign off. We did that for a guy that inadvertently (a term often used in medical mal cases: one meaning something like 'carelessly, without regard to ....don't use that word) put his garage on the right of way. We bailed him out by changing his easement. Tried to do it again for one family on a 15 A lot so they could have 2 sheep for a 4-H project and another to have 6 hens again for a 4-H project....two old biddies refused so they are stuck. Actually made a deal with the guys on their back fence and moved them over there!

The other way I did a long time ago in Wichita was to go around and photograph all of the TV antennas left over from the pre-cable days, I think there were 15 or so in the assn. Filed a suit naming the developer and assn stating that the covenants were already broken, that others were also violated, so the CCR were invalidated. Got a letter from the developer's atty that if I would withdraw the (not yet filed suit), they would let me keep the 30 ft tower with the KT-34. A quiet victory.

There are ways.

> Without doing any calculations I can tell you that your system
> is not going to be to 'Rohn' specifications.

That I know, but there was no alternative.
I can move the top tier anchor down to the concrete, and probably will, but that even with the extra tension exerts less side pull on the anchor than the lower guys.

> The primary reason
> being the guy posts.

Yup

> Two yards of concrete for the base is marginal.
> (I wouldn't think it would be but it is.)

According to the specs I have about the right anchor size for the tower (It's 30% larger than the weight of the one they list), but that would be with all anchors at ground level.

Actually I can move all of them except the lowest, down and there the clearence is required.

> It depends on the make up
> of the soil in your area, the amount of concrete used, and the shape
> of the concrete pier.

Good soil, (clay that is harder than a rock), two yards plus a tad in a rectangular shape. The tops are about 2 feet below the surface.

> Not being an engineer, my advice isn't the
> 'best', but 'Rohn' might help you (if you can get them to answer at
> all).

I used their book and a good safety margin with the guys and 30% on weight fot the anchors. (The mason gave me a figure of 5700# per yard which is 11,400#) I've also been working with a consultant, but second opinions are always appreciated (I have complete faith in no one <G>)

The man thing in my favor is that there is very little load imposed by the bottom set of guys except for the tension.

I can reinforce the pipe and put in a I-beam brace at about 30 to 40 degrees. That will take virtually any give out of the pipe and the anchor point will become the equivelant of the concrete. I've seen anchors similar that were made entirely from I-beam welded up, in much larger installations..

My point of contact with them was Jeff Moran.

So far the installation is fine with them except that elevated anchor. It'll hold, but reducess the wind load capability to about half, but they use quite a safety factor. It's already far more solid than the old 90 footer.

The problem is that with the heavier load we could run into oscillation I don't think there would be any problem should I stay with the same antennas as the old tower.
For this season I'm probably going to move the top two tier of guys to the concrete which will put virtually all the wind load directly into the concrete and eliminate the oscillation.

Reinforceing the pipe will *probably* be more than sufficient to handle the bottom tier as they are already rock solid. It's only with the addition of the tension fron the second tier (where the Kevlar is still springy) that I notice that tiny bit of spring in the post. It's not something you can walk up to the post and do. You have th really throw your weight around well up the tower (60 feet or higher) and with equipment I weigh about 190#. Even then I can barely feel any movement.

I'm using torque arms at the second and third levels and was told I'd notice some movement because of that. They prevent torquing, but add a little flexibility...

There is no movement down at the first tier which is the straight hook up without the torque arms.

Thanks,

Roger (K8RI)

If loops had some advantage, I'd sure use them for receiving! My best
receiving antenna remains my array of verticals.

Of course there might be cases where a loop puts a null in the
direction of local noise, so your mileage might vary. But the fact
it's a loop has nothing to do with S/N ratio.

As for gain, model a low horizontal fullwave loop and have a look. It
is essentially the same as a dipole on bands where it is close to
ground. On the higher bands, it has so many nulls you're as likely to
have a signal fall in a null as on a lobe.

That doesn't mean they don't work or work poorly, just that they sure
aren't some kind of magic cure-all. There is one neat thing that
happens, they have a reasonable impedance on multiples of the Full
wave frequency. Now that's a neat thing, compared to the wild
impedance changes of an all-band dipole from band to band. If I worked
multi-bands with one antenna, I'd consider one for that reason.

Looks like I can eliminate most of it when the Kevlar guys finish stretching
which should be soon and in addition I'm going to move all, but the bottom
tier of guys to the base of the pipe...Anchoring right at the concrete..

I'm stuck using the pipe to support the first tier at 10-12 feet above grade
and they, of course, put the most side load on the anchors which are
absolutely solid with out the added tension of the other guys.

Your reluctance to use a soldering iron or other "dangerous" equipment will severely limit your ability to homebrew even the simplest amateur equipment. You'll pretty much have to restrict yourself to what you can buy and plug together. I don't see any way you'll be able to build an antenna (or at least any reliable way you can connect it to your radio) without using a soldering iron.

Two comments, first the FCC probably can preempt CC&R's as it did for television antennas and satellite dishes less than one meter in diameter, it did it, and so far, the preemption has withstood court challenge, and Congress hasn't complained. 2nd, the FCC so far has declined to so preempt for amateur antennas, and it's one of the things that the ARRL among others keeps on pushing before the FCC. Amateur radio may disappear from most places not because hams get too old as one wag once put it, but rather because hams can't get on the air reliably with no antenna.

If prone to forgetfulness when having soldering iron on, think of a way to work around it -- could connect it to a timer, for ex. ... (Am very aware of fire safety, being the son of a former fire inspector/fire chief.)

Agreed Tom.
Beams made of concrete and reinforcement wires
are done that way for a reason.
I cannot understand why one
would use a hollow tube as a guy post without the addition of concrete.
I use 4inch diameter posts for at least 20 years on my fold over 45 g
and they are filled with compressed concrete and present no problem with

lifting or lowering my 80 foot boom and prop pitch rotor
which is quite heavy. But we may be missing the real point of the
problem.

Jason: You could use wire strippers for your only tool, and get some pre-terminated coax, cut one end off the coax, get some hookup wire, and use the wire strippers to strip the wire ends. Then use wire nuts to connect the hookup wire to the open end of the coax: one end of the loop to the center conductor, the other end to the shield.

To the rest of you guys: where's your imagination?

Real victims only wish to escape and get away.

"Special victims" can't wait to get their hands on you so they can harang you, insult you, belittle you, sue you, have you arrested, or even have you chopped up and fed to the lions. Special victims frequently assume special rights allowing them to use unusual means to get the job done.

Carried to its extreme, Kenneth McDuff mutilated and murdered eight women in Texas, yet met his final fate on death row complaining bitterly to the end that he was a victim of many forces. But, he wasn't an ordinary victim. He was "special".

If you are threatened in an aggressive fashion by anyone claiming to be victim in a setting where attendance is purely recreational and voluntary (such as this newsgroup), run like hell! They may be "someone special" looking for you.

Towertalk@contesting.com may be a good alternative for those who aren't "special".

488. multiband inverted L question..

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: Peter Bertini <commquart@erols.com>
Message-ID: <8nn3gtffj1@bob.news.rcn.net>
Source record: 182248

I am considering hanging an inverted L off of a 54 foot Rohn-Spaulding
self-supporting tower. The tower is not guyed.

What I am looking at is about 15 meters vertical, with the L horizontal
section being about 6 meters long.

This will give me .279 wave on 80 meters, and .513 wave on 40 meters. I
am thinking about housing a remotely tuned matching
system at the base of the tower for optimum matching on both bands. The
other option for 40 meters is a dipole at the apex of a
guyed sixty foot Rohn 25G.

What kind of DX performance should I expect from this antenna on 40 meters?
Using Reg's end-fed program, the losses look
very good, but what kind off radiation angle should I expect?

Second question. 160 meters would be nice; I desire something for casual
dxing and operating for the Top Band. The 80
meter L would ends up being about .132 wavelengths with an extremely low
feedpoint impedance of about 8 ohms at 1800kHz.
Resistive losses are horrible. Should I live with the losses and accept the
compromise? I could hang a second L off of the
tower with a longer horizontal section for 160, but I understand that
trying to run two harmonically related Ls from the same
tower would result in unwanted coupling ruining the performance of the
higher frequency antenna. My preferences for best
performance are about equal for 40 and 80, with 160 running third place.
Suggestions for other tweaks are welcome. The
horizontal run is limited to about 25 feet if I am to keep the end at 50
feet or higher.

>logarithmic function is easy to come up with, one which is truly
>logarithmic over a wide range, and reasonably temperature stable, isn't.

I think an accurate S meter is much easier with receivers that use DSP
for the last IF stage and to drive the AGC. Here you typically can't
use the analog AGC voltage directly for an S meter anyway, since the
analog AGC is usually being driven based on the pre-final-filtering
signal strength, essentially to keep the input to the DSP's A/D converter
close to full scale. To run the latter control loop the DSP doesn't
require truly logarithmic AGC response but rather only a degree of
stability and repeatability. The AGC voltage to gain response can
be programmed into the DSP based on calibration derived from the
actual characteristics of the amplifiers, whatever these might be.

Since the DSP is doing the last stage of IF filtering itself it will
hence also need to drive the S meter itself based on knowledge of the gain
it is applying to the analog stages plus the measured (digital) signal
strength after the final filtering is done. Since it inherently needs
to know all of this with reasonable precision anyway, an accurate S meter
(calibrated to whatever S-unit standard the manufacturer chooses) seems
to sort of automatically fall out.

Jeff and Jason,

Any attempt to build a small transmitting loop antenna without using a soldering torch or even a welder will be a waste of effort.

The current in a small loop is many dozens of amperes and higher. The slightest resistance in a connection will destroy efficiency.

With big antennas, you can get away with twisting and crimping connections, but not in small loop antennas.

I'd suggest writing yourself a note and posting it several places, saying "my blowtorch is lit" or "the arc welder is on". That always works for my wife when she is cooking. She wanted to give up cooking for the same reason, but the notes allow her to cook food without starting fires.

Actually, quite a bit of homebrewing was done in the 20's and 30's using
Fahnstock clips and terminal and screw connections on a breadboard.
Although there was usually some soldering involved, you could probably
get away with doing none, if you were creative. So, if you are up for
building a 210 TNT rig, you're in luck!

492. 40 foot crank up, tilt over tower FS in Florida

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: Ken Simpson <W8EK@fdt.net>
Message-ID: <jMEn5.2728$x16.189514@monger.newsread.com>
Source record: 182252

I have a 40 foot crank up, tilt over tower
available in Ocala, FL.

Presently, it has a KLM KT-34 A tribander on it.
It is not especially heavy duty, but obviously no
light weight either to hold the big 4 element tri-
bander. I would guess that it is home made,
although I am not certain of that. It is in fairly
good shape, but should probably have a coat
of paint before being installed.

The tower will crank down to about 20 feet and up to
about 40. It tilts at the base. Presently it is anchored
at the peak of a roof (about 15 or 16 feet), to hold it
in place and keep it from tilting over.

Obviously, someone would need to be fairly close to
the Ocala (north central Florida) area. I am looking
at $100 for it.

Thanks.

73,

Ken, W8EK

I can think of better things to hang, but that would be a good
antenna.

>What I am looking at is about 15 meters vertical, with the L horizontal
>section being about 6 meters long.

15 times 3.3 = 49.5
3.3 times 6= 19.8

OK, 50 feet by 20 feet.

>What kind of DX performance should I expect from this antenna on 40 meters?

It's a mediocre antenna for 40, but pretty fair on 80 if you use a lot
of radials. You are in a good location aren't you? It will probably
work OK up there where Europe is a stone's throw away.

A good dipole would be a lot better at 60 feet on 40.

>Using Reg's end-fed program, the losses look
>very good, but what kind off radiation angle should I expect?

I'd model the antenna and have a look. Some ground loss calculations
under estimate the real losses because they take an overly simplistic
view of what goes on.

>Second question. 160 meters would be nice; I desire something for casual
>dxing and operating for the Top Band. The 80
>meter L would ends up being about .132 wavelengths with an extremely low
>feedpoint impedance of about 8 ohms at 1800kHz.
>Resistive losses are horrible. Should I live with the losses and accept the
>compromise?

Why not put up a nice 40 meter dipole, and tie the feedline together
and work it against a nice ground system for 80 and 160? It could even
be an inverted Vee dipole.

Ever think about that?

Source record: 182254

Hi folks. I just set up my ham shack using a Kenwood ts-440s with a dentron mt3000a tuner going to w G5RV. I have a good size spool if #12 AGW stranded copper (insulated). Will that be a sufficient ground. it's going about 20 feet or so down to and across the floor joists and out to the ground rod that the electrical system is hooked to. there's no closer route to the outside and the ground rod is right there so there really aren't any other options. Unless you're going to tell me to sink a separate rod. I don't know so that's why I'm asking.

Also while I'm on the subject, the G5RV is about as high as I can get it in the trees, but the twinlead, which hooks to a balun and then coax will just reach the ground. Rather than having it laying on the ground I have it looped back up and the coax runs across the ridge of our roof and into the ham shack which is on the other side of the house. Any problems there, or rather, is it OK as long as it works?

Thanks for the help.

A soldering iron is not a dangerous fire hazard. Each iron comes with
a little metal stand that insulates the hot tip from the work surface.

You can also buy a soldering gun-- it heats up in seconds, solders
your joint, and then shuts off after you release the trigger.

Buy a soldering iron or gun, some solder, some wire strippers;
otherwise, forget ham radio.

I really don't get it. What is all this Fractenna stuff about. I've been watching this news group for a while trying to learn a few things from people's input on antennas, and all I read is this stuff (could have used a more aromatic word here to describe it) about Fractenna, lawsuits, patents, and God knows what. Why don't you all just ignore him. All you're doing is feeding him (or them... I haven't really figured it out) with a reason to argue and a whole string a subsequent replies and more name-calling and bitching...

This seems like poison ivy, scratch it and it still itches but spreads like crazy, ignore it and soon enough it will go away... hopefully.

The problem with the last ideal is that the coax runs are about 100 feet and
are run underground in 4" PVC pipe.

I suppose if I am going to go to the bother of a remote tuning box, it would
be feasible. I don't have a clue how to calculate
the matching networks since I don't have any modeling programs. (I knew I
bought that AEA HF analyzer
for a reason.) Wouldn't the average effective vertical height be lowered by
the average height of the sloping Vee dipole elements
when run on 80/40? What effect would a balun have--or should the balun be
eliminated in this particular application? It seems
like it (a balun on the dipole) would try todecouple the dipole elements
when the feedline is fed as a vertical.

Oh Wayne you have surely never had poison ivy onslaught!
How do you ignore it.? Please tell me more.
I am at the end stages of my second attack this year.
Being foreign born I am very much open to attack
without a semblance of an immune system since
poison ivy is native to North America.
Thank goodness there is no poison oak in this vicinity.
Could it possibly be that you never owned a stick
to slide down the cast when you last broke a limb ?

Nice responses, guys (Roy, Donnie, Steve, Cliff, Greg, Jeff, and Tom). Its nice to see so many positive responses, and humor, in this newsgroup. Give yourselves a good pat on the back (but don't get carried away with it - some might think it a little strange to see you hitting yourself like that).

And, Jason, I agree with them. It is going to be difficult to build an antenna without using a soldering iron at some point.

Well if you are feeling movement on the tower I would certainly anchor to the
ground
with that said the idea of posts seem redundent.If posts have to
be used and I particularly like them because the kids would trip over the wire
I would be inclined to still use tubular posts with concrete well tapped in for
compression
resistance and buckling prevention since it is the feel of excess deflection
that you are sensing
and the concrete should provide the stiffness required in your existing posts.
Combination of concrete with an I beam does provide a series of other problems,
If the I beam alone will not do the job I would look elsewhere
Standard thinking is to always stay the posts as Tom mentioned but it does
provide more clutter.
Ofcourse to be sure then one has to determine Second moment of Area for both
arrangements
and substitute in
M/I = f/y= E/r, at your own risk. Especially if you are unfamiliar with the
above series of structural calculations as aplied to beams in encastre
.

Wayne,
I wouldn't worry too much about an RF ground, not being on the ground floor, it would be 'tuff' to do. Just make sure you have an electrical ground and forget it unless you have RFI problems. You may or may not have problems by 'looping' the twin-lead portion of the G5RV. It should run clear of surrounding objects. But, as they say, 'if it works, don't fix it'. By the way, if that Dentron3000 won't tune it, it can't be tuned!

->nervous, but I haven't seen any failures yet in installations up to 250
->watts VHF after several years. It's an interesting idea. Does anyone
->else have any experience with this?

Yes. We used to use flooded Vaseline connectors with plain old sleeving tied with wax cable back in "the old days" before shrink and silicone. Other than a freakin' mess if you ever had to work on them after mating, they worked just fine and lasted forever. This was in the 120 MHz. range with powers of 25 to 100 watts.

Hi, OM:

If all of the pieces of the aluminum are *well-connected* to each other, you'd probably do better using the roof as a groundplane for a trap-vertical. I have done this in the past, after bonding the pieces on an outbuilding roof.

The ddrr (directional-discontinuity-ring-radiator?) isn't a good antenna unless it's scrupulously constructed with *large*-diameter stovepipe(!) ... do a google.com search on 'ddrr antenna' for a VE2something who really did the ddrr up brown; the site has impressive pix, and the chap may respond to email. Iirc, he phased 4 of them in some sort of array.

Lotsa luck what ever you do ... 73

I must agree with Tom- there is no reason a loop would be more quiet.
Many seem to think the 1 wave loop is an omni- it has a pattern almost identical to a half wave dipole with slightly less gain. On 160M my loop was a little narrower in BW than the dipole- same height above ground.

Hi Chuck--

I must confess that there are times when that sort of corruption is tempting.
But someone has to set examples and make progress. Few are chosen; many called.

Someone has mentioned a slanted H.

This H antenna is far worse--by almost 2 dB in field strength at low elevations(in this case at 10 degrees).

IF someone does not understand how to properly model an antenna, and gets 'different results', that is there responsibility.

Hi, Art:

Re your query:

Mosley calls it 'the Classic feed', or something like that. They had 2 pieces of '8U center-conductor-with-insulation-but-no-braid connected as a sorta-dipole *inside* the halves of the DEs of some of their antennas. No mechanical connection.

Fwiw, I always got good performance from the S402 -- its c-l inductors were on big ceramic forms, and if you hammered plastic blocks inside the element-to-boom tube centers and drilled them for the u-bolts, the elements stayed put ... but that's another tale. If I ever catch up with the economy I'll build a chinese copy if I can't find one to buy.

I have no doubt that many of you have experienced the corrosive effects you describe. However, I've used the off-the-hardware-store-shelf variety of silicone sealer (always the clear type) made by GE or Dow, for decades. I've taken apart connections that were sealed with the stuff and have never found anything but bright, clean, dry connections. Everything I've used smells of acetic acid. I wonder if there isn't something else causing the problem in some silicone compounds? I've never really used the stuff in an enclosed area, so maybe the corrosive material bleeds out if the surface is exposed to air and sunlight?

Usually, I wrap a connection tightly with vinyl electrical tape, then silicone over that. However, connections I've made where the silicone was in direct contact with PL-259 shells have never shown any effects from the silicone.

I'd check with the local ham club (members) as they should know the
ins-and-outs for tower installation in your area.

If you can afford it you will probably find construction outfits in the
yellow pages, but it will cost many times the cost of the tower to get it
put up.

Source record: 182282

Hi Ken, Dave is right, it's a poor antenna. The only portion of a DDRR that radiates is the short vertical portion, while the 'ring' portion is effectively only top loading to achieve resonance. The spacing between the ring portion and the ground plane versus wavelength is too small to permit radiation, and acts like a single wire transmission line over ground plane, in which the image of the wire forms the second conductor.

Dave is also correct in saying the roof portions would need to be secured together electrically for it to work as a ground plane, because currents induced must have a complete path to permit flow.

First time I've seen you on the NG Ken, good to hear from you. See you in DeLand when we return in November.

Roger,
If you would change the 'acetone' to 'acidic acid', I would
agree with you (but never had a circuit 'fall apart' yet).
I also found a substitute if you can't find silicon. I was
away from home and needed to seal a center connector on a dipole.
Went to Wal Mart, no silicon like I wanted. Was wandering through
the sporting goods section and found some stuff called "Shoe Goo".
I won't try to explain it, go read the instructions on the tube,
then you try explaining it (LOL). Anyway, tried it, and it does
work. It gets brittle after abotu a year, so it isn't a permanent
seal (but when you think about it, that's not a bad idea). It
also comes in handy for a bunch of other things......FWIW.

522. Center-loaded dipole question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: Brad <bdstrau@attglobal.net>
Message-ID: <399eb12f_2@news1.prserv.net>
Source record: 182284

Center-loaded dipole question.

I want to make a homebrew center-loaded dipole, but I'm a new ham and I'm not sure my idea is technically sound.

My plan is to begin with a 50-ohm coax fed through an SWR meter and into a 1:1 balun at the center of the dipole. From each side of the balum I would connect a tapped coil. And out of the far end of each coil would be a length of wire to serve as the dipole radiators. Then, through simple trial and error, I would adjust the taps (same on both coils) until I get a good SWR reading for the desired band.

Does this make sense, or am I just not getting it? Am I correct in believing that I need no capacitance in the antenna, only inductance? I can't find this scheme in any antenna books, but base-loaded ground planes appear quite often.

Thanks and 73,
-Brad (kc6tue)

jason_hsu,
Your still going to need a counterpoise of some type. A
metal plate just isn't practical on HF, size is the problem.
A counterpoise or two made from wire with a 'neutral' color,
might still be your best bet. Good luck....

Roger,
Without doing any calculations I can tell you that your system
is not going to be to 'Rohn' specifications. The primary reason
being the guy posts. Two yards of concrete for the base is marginal.
(I wouldn't think it would be but it is.) It depends on the make up
of the soil in your area, the amount of concrete used, and the shape
of the concrete pier. Not being an engineer, my advice isn't the
'best', but 'Rohn' might help you (if you can get them to answer at
all). My point of contact with them was Jeff Moran.

Tom is absolutely right. The only way to get someone like Chip
off the newsgroup is to totally ignore him. Of course, it may take
some superhuman discipline to keep from responding to his
puerile, irritating, little posts, and people should expect a
rising level of desperation on his part as his trolls are
increasingly ignored, but, it's the only truly effective
way to deal with him.

Hi Brad,
You have 2 variables here- resonance of the antenna and feedpoint resistance- simply tapping the coil for feed R will not resonate the antenna. So you need to find the correct antenna length in combination w/ the inductance to resonate the antenna- then locate taps either side of center for 50 Ohms. Finding resonance is easy w/ a grid dip meter or noise bridge,

Dale W4OP

535. Re: Center-loaded dipole question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <lUyn5.6238$uX.12090@newsfeed.slurp.net>
Source record: 182297

Did something similar, with two 8-ft CB whips and a piece of 6-in diameter white PVC pipe, on 40M, and its final form was with a single coil in the center, and the feedline connected to what is known as a 'link' of a few turns of insulated wire wrapped around the center of the coil.

Nothing is critical, such as wire size, just so it handles powers and physical strains involved. As a starting point, make the length of wire in the coil about 10-20% longer than its equivalent straight dipole length that it replaces. For example, I started with about 60ft of wire wound into a coil about 4in in diameter iirc, with the thing I made above. If you have the coil on a form, you can spread or contract the length of the coil while adjusting stuff as in the next paragraph.

The number of turns and spacing in the link (start with 4) can be adjusted for usable swr, once the resonant point of the antenna is found by adjusting the number of turns and turn-spacing in the loading coil.

Having said 'nothing is critical', I take it back. Your patience and perseverance is critical <BG> They will be tested!

Gimme a shout if you need additional consulting.

73 and GL,

Dave, K3BHJ

Hi Brad,

For a complete design of a centre-loaded dipole, including
the number of turns on the coil, various feeding methods and
radiating efficiency, download program MIDLOAD from my
website.

Best method of feeding is via a link-coupling over the
loading coil to a balanced or coax feedline of any impedance
you fancy.

Download program in a few seconds. One file only. Run
immediately. Input data on a 'what-if?' basis.

Regards from Reg, G4FGQ

555. Re: PL-259 SO-239 connectors, versus 'N'type.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <399ECAA1.FB1F7506@haertig.com>
Source record: 182317

A 3 db loss of signal in VHF FM communications systems is generally not noticeable and considered acceptable - it is swamped out by the spatial and temporal variability of the signal that is inherent in VHF (and UHF) propagation. Many commercial systems actually have much higher loss.

In most marine environments the most important design criterion is robustness and reliability. For relatively short and well protected runs RG-58 works fine. I would avoid cables with air dielectric like 9913 because of their susceptibility to flooding if the connector weatherproofing fails or the outer jacket gets punctured. A closed cell foam or polyethylene dielectric allows for the possibility of emergency repair if a connector gets waterlogged.

If solid outer conductor cables (such as Heliax) are used, a good deal of caution needs to be exercised in mechanical installation to prevent repeated flexure. These cables will eventually work harden and break.

As to connector weatherproofing, I have started using the 3M cold shrink products. They are a snap to install, easy to remove, don't leave a gummy mess on the connector, and can be installed over a wide temperature range. They aren't cheap, however. So far I have not had any failures. They are widely used in direct bury electrical splices.

One antenna manufacturer recommends flooding outdoor Type N connectors with petroleum jelly before connecting. I admit this makes me a bit nervous, but I haven't seen any failures yet in installations up to 250 watts VHF after several years. It's an interesting idea. Does anyone else have any experience with this?

558. Re: Help!! The unmatchable dipole...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8nld1e$3ia$1@uranium.btinternet.com>
Source record: 182351

Mike,

The size (uH) of a loading coil to 'shorten' an antenna
depends, in order of importance, on

(1) Frequency.

(2) The overall conductor length or height.

(3) The location of the coil along the length.

(4) The length of the coil itself.

(5) The diameter of the conductor beyond the coil.

(6) The diameter of the conductor before the coil.

(7) To a small extent, coil diameter.

Any computer program which ignores conductor diameters may
be useful but will be inaccurate. There is also the matter
of designing the coil, number of turns, wire gage, etc., to
meet inductance and efficiency requirements.

The location of the coil affects both radiation and
feedpoint resistances. It also affects radiating efficiency.
As the coil(s) are moved outwards from the feedpoint the
antenna radiation resistance increases, the required
inductance increases, but for a given coil Q so does the
coil's loss resistance. For a coils overall dimensions
which control its Q there is a location at which radiating
efficiency is maximised.

However, the location of the coil(s) is not critical. About
3/5ths of the way from feedpoint to the end is as good as
any. But whatever means of determining coil inductance is
used it will always be necessary to allow for a little
trimming of the end lengths because height above ground and
adjacency of the mast, tower, guys, has some effect.

Download program VERTLOAD from my website. By connecting a
pair of verticals back-to-back, setting the ground loss to
zero, the program can be used to design a loaded dipole
complete with number of turns on the coil. Feedpoint
impedance is exactly twice that of a loaded vertical mounted
above a lossless ground plane.

559. FM Antenna Test Results (for those who're curious in a technical sense)...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: "MonsterFM.com" <engineering@MonsterFM.com>
Message-ID: <8nlejv$3si$1@nnrp1.deja.com>
Source record: 182352

We've constructed and tested several different models of various FM
broadcast antenna elements.
The results of these tests, as well as our conclusions, can be found
at http://MonsterFM.com/engineering/fmant.html
By the way, these are true tests (as carried out with a true and
recently calibrated FIM, a spectrum analyzer, a Boonton "cold bridge",
and a Bird watt meter with a dummy load for calibration purposes...
This should alleviate ALL doubt concerning the best mode of LPFM signal
polarization.

>
>Any advice would be appreciated.

No worries about power - problems begin at >1500W on 144MHz, or >1kW on 432. Even there, a lot of the problems are due to amateur assembly techniques and recycled connectors. N connections that have no imperfections and are left alone can be very reliable, even at these high power levels.

It's true that N is much more waterproof than 259/239 (well, that's not difficult) but I wouldn't trust a bare connector for marine use. Equally, I wouldn't trust a heat shrink sleeve on its own. US hams can advise you on the grades of Scotch/3M tape to use for multiple wrapping. Having done all that, you might as well use 259/239.

One hint - try to avoid outdoor connections between a coax plug (any type) and a flange socket on the side of a box. That's an almost impossible shape to wrap with tape. Putty materials such as Coax-Seal will work, but make a mess of the connectors. It's much better to replace the fixed socket with a short length of coax coming out through a proper waterproof cable gland, and terminate that coax in a line jack. The jack + plug combination is a much easier shape to waterproof with tape wraps.

Pardon me for stating the facts, but the losses are real, and the
performance difference between RG-58 and LMR-400 at 150 mhz. is obvious. And
yes, I have installed several VHF radios, and I have measured the losses in
different types of feedlines. I may not have your "pedigree", but the
numbers don't lie. What do you want, max performance, or convenience of
installation? If "standard practice" is to use RG-58 for VHF installations,
then apparently the choice is for convenience of installation (unless you
are running a VERY short piece of feedline).

You never ever want to use vulcanizing sealers on lines, use something
that stays gooey.

The best compounds are things like GE dielectric compound silicon or
the stuff made for CATV systems.

Use a bit sparingly inside the connector on the threads. Use a heat
shrink with goo imbedded in the shrink, like CATV companies use
outdoors and underground.

If you don't use that, use good tape and cover it with vapor wrap or
auto body seam sealer that stays flexable.

Dave,

Life is an adaptive system.

Accept the fact that this is a big world, and not everyone will like you, and visa versa.

But that gives no one the right to use whatever steps--such as: impersonation; accusations of fraud; accusations of mental illness; accusations of bizarre sexual engagement; copyright infringement; inaccurate and deliberately misleading data comparisons; threats of getting someone fired; and on and on (just of the few of the issues in the last month) to IMPOSE one's will of 'getting someone off the newsgroup'.

I am here to enjoy myself and provide accurate and cogent info. As long as I am capable of this, I am happy to be here.

Hope this helps.

73,
Chip N1IR

Hi Jerry,

If we would all ignore Chip, his posts would probably get more and
more outlandish. Eventually, when he failed to get attention, he would
go somewhere else or find some other outlet.

I think what we all miss (I'm guilty of this also), is he enjoys the
attention. It doesn't matter at all if it is bad attention, or if you
prove him to a fool, he just loves the attention.

The worse punishment for Chip would be to ignore him, and act like he
isn't even there. No matter what he says, or what he does.

He is a troll, who enjoys being chased and called a troll.

NC's remarks demonstrating mastery-of-the-obvious SNIPPED

NC:

You're acting like a one-trick pony: more tiresome screed about conspiracy, victimhood, threats.

We'd like you to adapt your words and will exclusively to the big world of your dot-com, where, presumably, everyone likes you and your enervating screeds and bloviations find total acceptance and agreement.

We have a surfeit of accurate and cogent info and no need of your tiresome, preachy screeds.

It's not a case of liking you or not liking you. Your behavior on this NG could be described like that of a young puppy: no matter where one tries to touch the puppy, there's a set of teeth waiting. Some puppies seem to mature into ill-mannered porcupines.

Provide us yet another dithyramb in response to three questions:

1. Can you stay on-point in your answer to question 2.?

2. In what way or ways do you enjoy and find happiness in subjecting yourself to the NG-milieu of accusations you so wearyingly repeat and repeat and repeat?

3. Is your answer to Q2 off-point?

We await your rejoinder.

Dave -

#1 I would recommend Stainless Steel, but the brass will work if the Teflon grease is liberally applied to the threads.

#2 I would use the 3/8" mounts if possible, due to the larger roof area sandwiched between the mount and the antenna.

#3 In order to prevent drilling through the headliner, wrap a piece of tape around your drill bits approximately 1/4" from the drill point. This will keep you from drilling to far.

Just my opinions.

575. HF loop antenna close to ground

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:00:00 UTC
From: kmccoy@stetson.edu
Message-ID: <399e931e.547677@news.stetson.edu>
Source record: 182368

I have an interesting situation: an aluminum-roofed carport about 50 feet long, 15 feet wide and 20 feet off the ground, apparently designed to hold a very large RV. I would like to use it as a ground plane for a multi-band wire loop antenna. I have friends who have heard of an antenna design that might work--a horizontal loop riding a few inches above its ground plane--but we can't recall the name or the design specs. Anyone out there who can help with information and/or sources?

576. Loop Skywire, Thoughts Anyone?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 00:09:23 UTC
From: cathexis@erols.com
Message-ID: <399dcae0.210292992@news.erols.com>
Source record: 182326

Greetings,

The 2000 ed. of The A.R.R.L. Hndbk. lists a project to
throw up a 1 wavelength horizontal loop they call, " The Loop
Skywire." It's cheap, I've got the wire (500ft. roll of 14AWG ins.),
and the trees to throw up it up as a lop-sided horizontal Quad, in
effect. So ,okay go for it.

What I'd like is feedback on a couple of questions. First
is insulators. I can scavenge two egg-types but getting more
means basically a 2 hr. expedition and more money. They're not
a Home Depot / RS item unless I but another RS SW Ant. Kit.
Since the wire is insulated, how important are they?? Just to
counteract line tension by swaying trees?? Maybe I'd rather just
take my chances if that's true.

Secondly, this loop certainly gets a glowing review from
the Hndbk. Do you agree with it? Experience with it? To compare,
currently I'm using a 66ft. random wire 20ft up and I'm using it for
my reciever (RS DX-392). So this loop is for RX only. Not sure
how much higher I can get with the loop (especially if I have to
climb up and tie off insulators). Which is another issue: Even if
insulators are worth it, would it be better to go for max. alttitude
of the circuit and just forgo the insulators? I have at least two
possible "routes" to use; the first is a shade over 40M wavelength,
the 2nd a shade over 80M wavelength. I wanted to go with the
80M for broader band coverage. I'm a newly licensed ham and
don't have more than Tech. privs. right now so this is just to make
for some better DX'ing on my reciever. Seems easy and cheap,
what do you think?

THX,

Andrew

I want to make it clear that efforts to maliciously libel me and my corporate firm have recently produced a query from a major telecom company, in which one of their chief engineers stated he will not have anything to do with the technology--based on these comments.

I will state clearly and emphatically that this is compelling evidence for libel and likely lost income based on such NG posts.

The situation is very serious, and in my opinion, at this point deserves media attention on how the internet is being used to kill companies.

I would like to remind those who libel that ATT had one such person in Houston put in jail a few months ago for such manipulation. The precedent is there.

>

Kraus--not KRAUSS

See Cohen and Hohlfeld; Comm Quart (1996); and Cohen (1997) . References on the web site in a few days:

http://www.fractenna.com

and sub-links.

The physics is obvious: There are two current maxima. The rad resistance is higher and the effiency is higher. This is discussed in the FAQ on the web site.

The same result-- two current maxima; unexpectedly high rad resistance and field strength-- was reported for short monopoles by Puente et al in 1998.(Electronics Letters).

Go model MI2 yourself and see.

First thing to remember is directivity is the only thing that mattters on a receiving antenna at HF, assuming the antenna transfers enough power to the receiver that external noise limits reception. Directivity in this context includes polarization and pattern.

Unless the loop happens to have a higher response in the direction of signal than it does in the direction of noise, it will be no different than any other antenna. The gain of multi-lobed antennas is largely useless, unless you can aim the antenna so the lobes line up with the desired directions or null know noise sources.

If you can't do that, you are probably better off with a broad response antenna.

As a general rule, the higher and more in the clear the better. I'd go for all the height I could, consistant with the thing staying up. What the heck, give it a try the simplest way you can.

It's not quite that simple. You should probably get a lawyer to research your particular area. There are binding, non-binding, and partially binding CCRs. You might be faced with one or another depending on the local zoning situation. In addition, there is the issue of enforcement. You don't necessarily have to sign something in order for it to be binding. And be aware of the politics. For example, a developer can pretty much do as he pleases if he "owns the land and can cast a single vote for each lot he owns" and thus gives him more leverage than individual homeowners. Further, there are sometimes "vague" yet legal clauses that apply to situations where the "homeowners can have something declared undesirable by a majority vote of the board, not the homeowners" and it too is binding. In another part of the city where I live, there was a CCR forbidding ANY vehicle maintenance anywhere on the property. One homeowner was fined because he did some work inside his garage! He was not able to successfully petition the court that this was an undue infringement. And by the way, the fact that somebody has a boat parked in their driveway, a camper parked in the street, or a car up on blocks, is no guarantee that a ham antenna won't be objected to. Best of luck.

And if you are going to ground the tower, it should be done early. When the hole is dug, drive the ground rod into the lowest part of the hole. Solder/weld a heavy braid to it, encase it in plastic tubing or wrap with tape to prevent the curing cement from attacking it, and then attach it to the base before the concrete is poured. When a ground rod is put next to a tower, seems like the lightning doesn't like the right angle turn at the base and it will continue to go down into the base. Just another thought...

Theory and my empirical data do NOT support the notion that all signals will be down with a loop antenna compared with all other antennas. I have some data plots that will confirm this from many contacts over an extended period of time comparing a full wavelength loop with a vertical antenna. Two plots exist, one for transmit signal strength, and one for received signal strength. The findings: the loop far outshined the vertical close in with a difference of as much as 15 db or so. As the distance increased between the stations the differences decrease until both antennas were equal at a distance of 1,000 miles. Beyond that the vertical took over.

On receive, the loop produced 1-2 S units of less noise and signals could be heard with the loop that could not be heard on the vertical.

I would be happy to send the Excel plots to anybody who is interested. I'm working on an article describing the results too but haven't finished it yet.

Just one ham's data.

587. Guying towers and moment

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 02:27:19 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <bgmn5.2556$x16.176324@monger.newsread.com>
Source record: 182338

OK, for the engineers, or mathematically inclined...

I've installed a Rohn 45G, but due to a driveway I had to raise the guy anchor point 10 feet and do it on all three anchors to keep the system symmetrical as well as out of the way.

I did this by using five inch diameter heavy wall steel pipe which sets in two yards of concrete, the base of which is six feet below grade. The anchors are out 80% of the tower height., or roughly 80 feet. (79 is you want to be specific)

The guys are tensioned to 10% of their breaking strength or 400# for all guys on the bottom two tier (31 and 65 feet elevation) and 600# for the top tier (96 foot elevation).

Now, to those who have installed towers up to 50, or even 60 feet, this probably sounds like a rather sound guying of the installation and they are sturdy...Unfortunately at 90# per section of tower and all that guy tension they are also just a wee bit flexible as are freshly installed Phillistrand guys. Not enough to really notice while climbing the tower, but (without taking the time to calculate the horizontal pull 10 feet up, on the 300# pipes set in over 11,000# of concrete) that horizontal moment is substantial and leads to a tiny bit of flexing. (it don't take much)

If you place a hand on any of the guy anchor posts you can feel every touch of the wrench to bolt, or every step from tower cross rung to rung.

Most of the stretch, what little there was has pretty much been eliminated from the bottom tier of guys. The second tier is getting better.

The top guys will come in steep enough that they can be anchored right at the top of the concrete pier, or base of the five inch pipe. It will have to be offset far enough that the guy lines will not rub where they cross.

As the goal is for three independently controlled arrays on the tower, the flex must be kept down to an absolute minimum. The HF array at the top of the tower will be roughly 18 sq. ft (and near 200#), with a 6 sq. ft antenna about 12 feet above that ant about a 4 sq. foot array 12 feet above that. The stretch in the Kevlar (Philistrand will pretty much be eliminated after a couple of weeks at tension...Actually they are retensioned at roughly three, seven, and 14 days after the initial tensioning at installation.

The five inch diameter pipe is a more interesting case as tightening the guy lines properly puts the pipe/system almost "in tune". Over tensioning can make for a very interesting situation. Similar situations can be found it steel guys are not properly positioned and tensioned.

Here, "I'm thinking" of changing both the resonant point and rigidity of the pipes by possibly :

1. inserting three re-rod and pouring a rich mixture of concrete into the pipe.
2. Inserting an I-beam that will just fit and again pouring in concrete, or
3. Welding I-beam to the front of the post to reinforce it and again filling the pipe with concrete.
4. Respace and add a 4th tier of guys?

Concrete by itself can be very flexible.
I have a 3" pipe set in the ground to support an 11 foot satellite dish for tuning. With the weight of the dish that 3" post will oscillate at a rate between one and two seconds per cycle and at an amplitude of about a 4" swing at a height of 6'.

The system will work as is, but I want to make the tower as rigid as practical.
I'd hate to find that a given load and wind would hit a resonant point.

Any suggestions?

>or the feed impedance?

The wire induces a current on the inside of the tube, which flows in a direction opposite the current in the center conductor. It spills arouund the ends and flows across the ouside, of course reversing direction so it parallels the current on the inner conductor.

The end effect of this is you add a bit of extra loss resistance in series with the original conductor, and change its surge impedance a bit.

That could only be because the loop happen to have a null in the
direction of noise that made noise reception less than the response to
desired signals.

At HF, gain doesn't matter for receiving unless the system has extreme
sensitivity problems.

Loops are not more quiet than any other geometric form, unless the
antenna happens to respond less to the direction of noise compared to
response in the direction of the desired signal.

Generally a covenant is in place and can be part of the deed, or attached to the property, such as a subdivision.

If you purchase you are in effect agreeing to it.

Zoning on the other had at least gives you a legal fighting chance...Up to a point. When it comes to safety such as set back ordinances and requiring engineering for "larger" towers they are quite legal and are not preempting FCC authority. OTOH if the zoning contains arbitrary heights and prohibitions you again have a chance.

My advice "for what it's worth" is to avoid any area that has covenants, or associations that limit what you can do within the realm of reason.

593. Sheet of metal as a ground plane for an antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 03:13:59 UTC
From: jason_hsu@my-deja.com
Message-ID: <8nku1ehml1@nnrp1.deja.com>
Source record: 182345
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.antenna

I think I have an idea on how to ground an antenna for the apartment HF shack I still haven't equipped yet.

Some of the things I have learned in my 007 mission to obtain the equipment I need to operate HF:
1. Unless I use a balanced antenna (like a loop or dipole), I must establish a good ground/counterpoise. How important this is depends on whom I talk to.
2. In mobile operations, the vehicle itself provides a ground plane. Thus, there is no need to mess around with ground rods or 1/4 wavelength radials.

I am seriously considering using a Bugcatcher antenna at my apartment. Can I use a sheet of metal (or a metal screen) instead of my car as a ground plane? If so, how large and thick must this sheet of metal be? If this setup can work, I can have a good temporary HF installation that I can bring inside when I am not operating. The fact that I live on the ground floor with no bushes or trees to conceal wires means that I cannot have an outdoor antenna that is sufficiently stealthy. The alternative seems to be a temporary installation that I keep outside only for the few hours per week I expect to operate.

Couple of items.
If the silicon seal smells like acetic acid? It's the corosive stuff.
Don't put it in contained areas.
Where I used to work we purchased a whole bunch of transducers potted in the
stuff inside cast aluminum boxes.

About a year later they started going bad.
Sure enough, when we started takeing them apart we found that most of the
foil was gone from the boards. Well over $20,000 down the drain plus labor
which made the $20,000 look like chicken feed.

Get the stuff that "stinks", but not the black stinky stuff as it is
conductive.

I believe both GE and Dow Corning make the non conductive stuff as well as the regular. I know DC does as I worked for them well over 30 years. That is why I also know that if it smells like acetone it's corosive.

I use DC-4 compound and fill the connector, then like Jim, I head the shrink tubing from the center out. Actually I do each end first, then move to the center and work out and use a piece of tubing about five to six inches long.

I have used the "bathtub calk" which is usually corosive and had it eat the plating right off the connectors. (smelled like acetone)
Also, that stuff cures by moisture so if it cures inside the connector within a few days you can be certain that the connector was not moisture proof, or well sealed, heat shrink tube, or not. Then again, the silicon rubber (such as Silastic RTV @) is water proof, but not moisture proof.

But...As I said, it is water proof and will keep salt out as well.
>

I've even used the bathtub calk to seal coax to dipoles and it turned green where the stuff contacted the copper wire. Course out there and with heavy wire it's not really a problem, but finer wires, solder, and foil in contained spaces are bad news.

596. Bathtub calk, building selant, and other RTVs

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-19 03:54:14 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <Gxnn5.2567$x16.178003@monger.newsread.com>
Source record: 182347

I thought I'd put this into a thread by itself.

From time to time some one will mention the use of Silastic RTV @, or other brands of silicon sealant for use in amateur Radio.

Much of it works great and there are other materials out there that work well too.

I'd assume that the acrylics work well too, if given a chance to fully cure before being put out into the elements.

A major word of caution though.
Any of the RTVs that smell like Acetone do so because you really are smelling Acetone.

In confined places with prolonged contact, Acetone is corosive to copper, aluminum, and solder.

There are a number of RTVs that do not use acetone, but rather alcohol and possibly other agents. In general they use the moisture in the air to aid curing as do those that smell like Acetone.

I've heard salesmen get really excited and claim that "their brand" is not corrosive, but if it smells like Acetone... and theirs did!

As I mentioned in another post, one company ended up with a very large expense because they were using an RTV (that smelled like Acetone) to pot some transducers and printed circuits in some cast Aluminum boxes.

A year later the circuits started failing and dismanteling showed that the wires, printed circuits, and solder joints were just crumbling away to be left by a white (or green) powder.

I "prefer" to use DC-4 compound *in* connectors. It's a dielectric grease that was developed in WWII to fill the spark plug connectors in B-17s and other aircraft to keep them from arcing at high altitude.

The stuff is clear, but *messy* and expensive. Some antennas come with a tiny capsule of it and no, I'm not talking about Pentrox. It does form a film that stays and prevents oxidation.

I also use the Marine "Liquid Electrical Tape" which works great. Doesn't last long after the can has been opened, but works great. I usually run out, before it drys out any way. <:-)) It's not very expensive either.

When using DC-4, I typically fill the connector with DC-4, make the connection which squeezes grease all over. I try to keep the grease from covering the outer surface of the connector. Then clean up and give the

connector at least three coats of the liquid electrical tape. Allow plenty of dry time between coats.
No, I've never noted a problem with an impedance bump using the grease in the connectors and I checked a few with a time domain reflectometer.
You do have to give the connectors a thorough cleaning after the grease though or absolutely nothing will stick. <:-))

For most work, I just use the liquid electrical tape. On UHF connectors you want to make certain that the entire connector is covered after assembly. Water can get in either end.

When using 9913 or similar cables I use the grease as water in one end will run right on out the other and the normal connectors only slow it down a little.

There is a stain on my operating desk right at the back of my two meter rig from where the water was dripping on the desk.
I hadn't filled the connectors and a lightening hit took the tape off the outside of the connectors up on top. That leak cost me nearly 200 feet of 9913.

There's a type of silicon seal that doesn't smell like vinegar and
which is totally waterproof - it's used to assemble aquariums. Get it
at any pet shop. The "vinegar" smell is acetic acid - nasty stuff
around metal. Best not to use it.

Just so I'm sure I have it right, 100% weight is no time off
and 0% weight is no time on. At 33% weight, the dots would
be separated by an off period twice as long as the on period.

I.e. weight = dot length / (dot length + space between dots length)

>Anyone out there that actually like the Outbacker for HF Mobile operation?
>Is it really the much worst then say a Pro-am whip or Ham stick?

I suggest the oubacker is a sturdy antenna, one you could probably take off your antenna mount, beat a pack of wild dogs to death with and then connect up and have approximately the same antenna performance you previously had. That being said, it is not a stellar HF mobile performer, its performance on 75 meters is well below that of a screwdriver, large bugcatcher, center leaded whip (ala for example Hustler) or the tapered whips used by folks like Hamstick, Lakeview et al.

It does have some usages. Ham truckers who regularly have to switch trucks might find them useful, since they can be easily moved and offer multiple HF band access, someone who drives a company vehicle or rents probably will find them of use (no holes, no worries about excessive bending of car parts). If you fall into either category, the Outbacker is for you, but for best performance on 40M & 75M, you probably want a screwdriver or BugCatcher, if they're too large, next in performance is a center loaded antenna, then the spiral loaded whips. There are of course small HF center loaded antennas like the Comet antennas which have a variety of performance problems which fall in between "normal" center loaded and spiral antennas, and finally things like the OutBacker, and base loaded whips. It's your choice. If appearance or size is very important, then perhaps the OutBacker is for you, but with a known performance deficit.

608. What Is The Theory Behind This Grounding Method??

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 00:00:00 UTC
From: Jim Bo <jbollit@ix.netcom.com>
Message-ID: <39A033D6.83A7F750@ix.netcom.com>
Source record: 182076

Hello,

I read many many years ago about a method of grounding a ham radio transmitter that is located on the second floor of a house.

It involved using coax. The dc path for the ground was the center conductor. The "different" part of this method involved taking 0.001 microfarad caps and connecting them at each end of the coax from the outer braid to the center conductor. There was no dc connection to the braid, but at each end the braid was connected to the center conductor via the 0.001 microfarad caps.

This was supposed to make a better rf ground for the radio located on the second floor.

Does this make sense? What principal is in effect that makes it "sense?

Thanks in advance.

Jim

Sounds like a good April Fool article. Connecting a .001 mfd cap from
center conductor to the braid will create a very low impedance path at
radio frequencies. Essentially a short circuit.

If your neighbor is getting TVI, this would cure it when installed on
HIS coax. :-)

Howdy Guys
I have a Valor 40m whip that has a SWR of 1:6 to 1
I had to wind a coil around a 2 inch piece of PVC pipe.
I used number 14 bare copper and wound the coil using
string trimmer line as a spacer and when the glue dryad
I remover the line for a evenly spaced coil .
It works ,but its sort of big .
Can you guys give me so better ideas on making a coil ?

Thanks

The cable manufacturer recommends that the cable be tensioned to 10% of
its rated load. Presumably the tower manufacturer's recommendation is
for that size cable (or equiv.).

SSB,

I don't know if you'll consider this helpful or not.
You know what it's like when you've got a couple hours
to kill and so you dial up and start surfing the web only
to find that you've gone from link to link until you've no
idea where you are? (Happens to me all the time)<grin>

I'm positive that I've seen at least two sites out
there that do show indoor loops for HF and/or plans.
That's not much to go on. If I've time I'll look around
some myself. I have print-out for a BCB AM loop
around somewhere. I'm sure it's very possible to do it
for HF. Interference is another issue. You're in a gnd
floor apartment-- Maybe you've got a buddy on the
top floor? No. Maybe time to make a new friend.

Instead of using a coil you can use a variable capacitor to ground- you will need to increase the length of the tip in order to make the antenna look inductive. Start off with a 365pF variable and adjust it and the antenna tip until you obtain a match. Then substitue a fixed cap (hi voltage) in place of the variable.

Group:
The rate of dissipation of acetic acid from curing RTV is dependent on the cross section thickness. Thin sections, like coating a connector when left to cure fully, are often not corrosive. Potting something and then immediately putting it in a sealed box guarantees that the acid will be around long enough to cause major trouble. So, it is the thickness and exposure, and both anecdotal comments are likely correct. I have experienced both conditions with Dow Corning 732 over the years. I also have found that the non acetic acid types like Dow 734 and 3140 are not as physically robust as the 732, and suffer mechanical damage if not protected by a jacket.

Andrew:

Actually, my neighbors and I don't speak much. Everyone pretty much keeps to themselves, which is one of the reasons I like this place so much. It's also not just a ground floor apartment.. it's below ground. The top of the ceiling inside the apartmentis maybe 8 inches off the ground, tops. Maybe I could use the rain gutters to run some coax up to the roof, and run a loop or something around the edge of the eaves, or maybe use the raingutter itself as an antenna.

I don't know... I'm just looking for the easiest to execute, yet most efficient antenna design I can possibly get while still keeping in mind that it needs to be nearly invisible and the fact that I don't move around so well. All of your ideas have been wonderful, and I greatly appreciate all of the constructive input you and others here on this NG have offered. I suppose I've just got to kick it around in my head a bit and see what falls out. (Hopefully it won't be that plate!)

Butternut antenna's are now built by Bencher. The address for manuals and information is http://www.bencher.com/ant_select.html . You can download the manual free of charge. If you can't get the door knob capacitor required from Bencher you could order one from some other company that offers these capacitors for sell. If I remember right it's a 67 pF capacitor. While your at it look at http://n4zou.homestead.com/files/butternut.htm . Here you will find information on building a remote tuner for your Butternut vertical. the tuner is very simple, it is only a motor driven capacitor placed across the 80 meter coil. As the bandwidth is only around 80 KHz on 80 meters you wont be able to use the antenna for the entire 80/75 meter band. With the remote tuner installed on the element of the Butternut antenna you can tune that 80 KHz anywhere in the 80/75 meter band that you would like to operate with a simple control box in your shack. It also has an effect on 40 meters and allows you to tune that band also. All the information is printable and you may save it to your system to view off line as you like. 73 and good luck.

rattlehead,
For what it's worth, it sounds like the problem is in the
antenna switch. Does the switch ground the unused position?
If it does, can you 'unground' or 'unshort' the vertical when
you switch out of it's position? If the switch doesn't
short or ground the unused positions, try grounding them.
If that doesn't help, well... don't connect the vert.

It actually does help in some sense. It helps answer the (mostly
academic) question of whether manufacturers build useless S meters
because it is too hard to build accurate ones, or whether they build
useless S meters because the manufacturer doesn't give a crap about
the accuracy of the S meter. With the final IF implemented with DSP
I don't think the problem is that it is overly difficult to build an
accurate S meter.

>These are the results for the new IC-756PRO, taken from an RSGB lab
>review (values below S9 are averages of measurements taken every 2 S-
>points):
>
>S1-S3 1.9dB

>S7-S9 2.4dB
>S9 - S9+20 13.0dB
>+20 - +40 22.1dB
>+40 - +60 17.9dB

This is neat. I can think of two obvious methods that could have
been employed to achieve this result. They could have gone to the
trouble of explicitly programming the DSP to produce S meter readings
that are compatible with their previous products, or they could have
just left the S meter attached to the analog AGC circuit. In the
latter case the S meter may now be responsive to signals outside the
digital passband, making it even worse than it was before.

In any case, I don't disagree that most S meters are mostly useless.
I was only commenting on the relative difficulty or ease of making
them useful.

I recall the article in 73 or Ham Radio Magazine. They did some
"explanation" on the theory, however I do not recall what the theory was.
The article was in the early 1980's.

Board OKs Puffy's Annual Bash

by Seth Stern
Staff Writer

Hamptons A-listers and celebrity gawkers take heart: Rap mogul Sean (Puffy) Combs' Labor Day party will take place after all.

The East Hampton town board reversed itself Thursday night and approved a permit request for Combs' annual bash that last year featured live salsa music, a Mr. Softee ice cream truck and a "Who's Who" of the Hamptons.

Town Board member Diana Weir, whose vote in the 3-2 decision tipped the scale in Combs' favor, said she changed her mind when Combs' attorney moved up the close of the festivities from 1 a.m. to 10 p.m. The board initially rejected Combs' application at a meeting Tuesday night. "He made an accommodation, and I figured we'll give him this chance," Weir said Friday. "If he violates it, I doubt he'll get any more permits." Town regulations mandate board approval for gatherings of 250 or more, said Town Supervisor Jay Schneiderman.

In past years, neighbors complained that guests such as Jennifer Lopez, Martha Stewart and Susan Lucci, along with hordes of their fans who linger outside, clog local roads and stay noisy late into the night.

Combs' next-door neighbor Debra Lobel, who said party preparations make it difficult to sleep for days and interfere with her own anniversary celebrations, criticized the decision.

"The town board has folded even though he's had violations and he's been a most inconsiderate neighbor," Lobel said. "They are bending over backwards to give the celebrity what he wants to the detriment of the quiet enjoyment of the neighbors." Combs paid a $2,000 fine following his 1999 July 4 weekend party when festivities continued past the original 10 p.m. ending time.

Combs' attorney, Stuyvesant Wainwright IV, said his client wanted to "be reasonable and keep the disturbance to his neighbors to a minimum." Last year, the board also initially rejected his application for the Labor Day weekend party, but reversed itself after he made concessions.

Try using B&W coil stock. 2-3" diameter, 2-4 long, 6 turns per
inch.

Grounding unused contacts is usually built into the switch. If it
isn't made that way to start with, it's very difficult to change it.
It
will probably affect your slopper, but I'd ground the antenna switch,
May
not make much difference as far as the antennas are concerned, but
does
make a difference for safety.

I am about to get pounced on for going off-topic, I know. Political leaders should set examples of social, or public morality. Personal, or private morality is nice, really beside the point. The failure of the government and the public to understand the difference hold sus back and leads us into a lot of quagmires of bad policy. I don't think social morality precludes the personal, but it amazes me again and again that the rhetoric calling for a return (from where, from when?) to private morals in public office offers as its obverse a venal, self-interested, amoral (as in no morals, good or bad: business is business after all) view. Good thing the electorate isn't as dumb or malleable as its reputation.

I seem to recall the same thing. This "technique" was to make the ground lead look shorter at RF so you would have, in effect, the radio "close" to the ground rod.

Can anyone model this to determine if there is anything to it??

Tnx

Jim

A tuner would probably not do you much good. A preselector might help but before buying or building one of those, put an attenuator in line. It sounds like you are having overload problems. Take a look at my website, there are a few thins there that might interest you.

Jason,
The 'OutBacker' is probably no worse and no better than a
'Pro-Am' or 'HamStick', in performance. Price is an entirely
different matter! The 'OutBacker' may be a fine antenna, but
not $300-400.00 worth better than either of the other two.

Doc, electrical ground (the lug on the back of the set) is the one I'm speaking of. If there isn't one hooked up, I will get RF around the equipment in the shack and a loss of performance... no?

... I wonder because in the ARRL Bible (which should have some more common knowledge because it's what a new ham buys first) it says not to hook it to water pipes (we're on a well anyway), so I was curious about the wire size needed (12 awg), and if a common ground rod shared between the house AC and my radio was a problem.

645. Clarification of my question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 00:00:00 UTC
From: Wayne Grauel <wgvideo@attglobal.net>
Message-ID: <399FCEF6.66815706@attglobal.net>
Source record: 182124

I'm not talking about a ground plane here for the antenna, I'm addressing that ground lug on the back of the radio and the tuner. Plan on using #12 stranded, insulated, copper wire. I was going to send this out (about 20 feet) to a common ground rod that also serves as the AC ground for the house electrical system.

Sorry if i wasn't clear.

Wayne

>
> 73's
>
> -SSB

I think the length your thinking of is greater than 15 wave
lengths. After about 15 wave lengths a longwire antenna becomes
'aperiodic', and very broadbanded. You don't need a balun because
a longwire is not a balanced antenna. You would need a variable
harmonic filter to feed the antenna (tuner). You will also need
a good ground system (depending on who you ask). A longwire
'should' be as high as possible, not close to the ground and
definitlely not under ground.
Once you get above 4 - 6 wave lengths long it starts getting
directional, but it has a very broad directional pattern. This
pattern isn't too predictable, so 'aiming' a long wire is almost
impossible.
At 15 wave lengths, your talking about one long antenna. On
10 meters, about 500 feet long, and on 160 meters, a bit over a
mile and a half long. Can't squeeze that into my city lot...

AMEN... I'm new to this also (if you're not) . Makes you think that ham operators are a bunch of assholes sometimes... not like the good old days. My dad loved radios and planted the seed for me. The impressions I had of Ham operators was one of people who people who were professional to the degree that they accomplished their goals, and were polite. Not like the world of CB Radio today, but rather a code of ethics that seemed to adorn people who were into such a demanding hobby. OK... I didn't have to copy 15 WPM to get my General ticket, but I passed the Tech Plus years ago. Maybe if I waited till I retired, I would have had the time to devote to bringing my code up to 15 WPM, but I have to work long hours so My wife can stay home and raise my two boys. Some things have a priority, and admit it.... things were different back in the good old days, life was kinder then, so If you've all got a grudge because someone has newly acquired a license or an upgrade... (this is what it sounds like so forgive me if I'm wrong) I suggest you get over it. I would suggest that the radio companies are loving life right now, and you guys who want to buy really expensive equipment should be darned glad there's some new guy out there to take it off your hands!

And, then again, maybe this isn't the case... maybe the person who made that ridiculous reply (I don't know anything compared to you guys but I do know he was giving this guy a line of garbage) is one of those CB'rs become HAMS. Even I dread that and don't want to see that. 2 meters is full of them.

What ever the case, people like that certainly stain the images of the rest of us who just want to be in the spirit of ham radio..... or did that die a generation ago!

Jason,
Here are a couple of suggestions for ya. Get with some of the local Hams, and find an Elmer to help you out. Another would be to take a basic electronics course at the local community collage. This won't cost a whole lot of money and It will make you alot more comfortable with not only an iron but with the workings of ham radio as a whole. I have a 3 soldering irons I use here and one of them is the trigger type that oly heats when you pull the trigger, it has a rapid cool down. This would be perfect for you as you would be working only on "BIG" connections not the insides of a rig. Give it some thought a soldering iron is probably the most used tool in antenna building, and the easiest way to learn how to use one is practice.

Thanks for that insight on weight, Tom. I am working on a contest logging program and thought that that weight was the ratio of dot & dash/3 length.

I looked it up, and I believe that it is the ratio of dot to (dot + space) length.
Dash remains 3 times the dot length.

That should help improve the sending of the program. The web page for the program
can be seen at:
http://tomwagner.home.mindspring.com/n1mm.htm

Take a look, you might be interested.

SSB,

You might be helped by two recent threads here called Project
Skywire and Loop Skywire. It is one type of longwire and the thread as
well as the compromises I had to make give you one approach for you
to consider. I'm sure the Old Timers here would tell you almost any ant.

is better than no antenna. What do you have now? I went from the whip on my portable rx., to a 23ft. retractable to a 66ft. random wire, to a 200ft. sorta loop. Each step has brought me substantial gains as well as penalties (I heard LW best on the 23ft reel-in). Hope this helps.

Hi Jason,

I have an Outbacker for travel. It is significantly down in
performance from a bugcatcher or screwdriver but it is
much easier to carry and install on a rental car. Used with
fishing line guys it works just fine with a trunk lip mount.

It is more expensive than the hamstick option but it is much
better construction and more convenient than carrying numerous
sticks.

At the antenna shootout in Santa Barbara it was about 8 db
down from the screwdrivers etc. on 75M. This difference
is less on the higher bands. If you travel by air is it a solution
for the rental car.

HI Jason, Igot the same results from my survey...the most disturbing reply, said you must RETUNE the stinger everytime you change bands..that would be awful...let me know if you get any real DIRECT info...I never did...still would like to try it but my hamsticks are so cheap and easy and good....$300 for a whip seems high!!! plus I have to get the hi powered one...using 40 and 80, 100 watts wont cut it but 350 - 400 makes it very viable...sure would be nice to jump from 40 to 17 in the day time for a few minutes to see whats up!! 73 murray

>the latter explanation best fits the circumstances.

Always ready to believe the worst of other people, aren't you?

If you took the trouble to read the review yourself, before telling us
all about it, you would find that:

10dB S+N/N = 0.16uV
S1 on the meter = 1.6uV (both figures on SSB, 7MHz, preamp 1 in)

In other words a signal has to be about 30dB above the noise floor
before the S-meter will move past S1.

At the strong-signal end of the range, a receiver's performance will
degrade in several different ways, each defining its own separate
dynamic range above the noise floor. None of this has anything to do
with the S-meter having gone to maximum.

So the problem is entirely with the S-meter, not the rest of the
receiver... and it's certainly not with the RSGB reviewer, G3SJX, who
knows exactly what he is measuring.

His response was serious (theoretically) :-)

My most serious suggestion would be to invest 30 dollars or so in
either the ARRL Radio Amateur's Handbook, which has several chapters
on antenna theory and construction, or get the ARRL Antenna Handbook.
You're flailing in the dark here with really basic questions that can
easily be answered by studying one or two books.

These books will also hold you in good stead, in your studying for the
ham exams.

To check out the books, go to http:www.arrl.com and click on
"products."

Have a good day,

Hi Tom

I don't think my Benton Harbor Lunchboxes came anywhere near 100 amperes, hi hi......

Even my biggest rig an HW-101 with approx. 100 watts out wouldn't come anywhere near 100 amps, more like 1.1 amp tops, unless ohm's law is really screwed up.

I also think the clips would outlast the 26 guage copper magnet wire as well.

Hi Ian

Some fears are quite REAL, no matter how rediculous they may seem to others, or sometimes to your own self.

Since I'm the scapegoat here today, I will use myself as an example. At one time (pre-35) I had so little fear of height that I had a part-time job replacing the lights on broadcast radio/tv towers. Once I crossed that 35 mark, I either wised up some or decided the best place for my feet were on the ground. However, I still had no fear of height.
Then when I was around 48 years old I had an accident, a new commercial ladder snapped and I fell over 35 feet to the ground below. I was not seriously injured, or at least I didn't think so, but something psycological snapped.
The next time I climbed a ladder, my hands froze to the ladder at about the 12 foot point. Being of sound mind I tried to climb back down the ladder, but my hands would not let go of the rungs. I'm even standing there talking to myself, boy this is stupid, let go you dang hands. They wouldn't! I finally took my feet off the rungs and just dangled by my hands, thinking they would tire eventually and let me drop to the ground. They didn't. Eventually, someone called the fire department who tilted the ladder over, when my feet touched the ground, my hands let go.
A little experimentation proved that I could go about 10 feet with no problems, over the course of a few years, that 10 feet had lowered itself to 8 feet. I even went to a shrink a few times to discuss the problem with him. In my line of work, it was a serious problem.
About 4 years ago, it happened again at only 6 feet, and I went through the dangling routine for over an hour with the tips of my toes touching the blades of grass on the ground and my hands would not let go, until someone tilted the ladder enough that my feet were planted on the ground. Needless to say, I was embarrassed moreso than ever and decided to retire from that field completely, before I was laughed out of it.

Now if our friend has a real FEAR of a soldering iron, it could be simply from lack of knowledge of the device and can learn it's safe operation, or it could be a real instilled FEAR that may prevent him from ever handling a soldering iron.

In either case, having a knowledge of the alternative methods at his disposal would be more beneficial than offering none, other than learning to use a soldering iron.

FWIW - we have built whole chassis using nothing more than a wire-wrap tool and no solder ever touched the entire radio. I know those days are long gone now, but it was still an alternative method.

>
> A single relay will switch the system, or you can use two feedlines.

> This idea is patent pending and I'll sue....oh never mind.

>
> 73 Tom

1: The choke balun construction eludes me, since balanced line
precludes winding the line into a choke as can be
done with coax. Ditto for placing beads over the balanced line, and I am
sure you are not talking about a 1/2-wave coaxial
4:1 choke balun. Give me a bone.

2: The relay is a DPDT, one set of contacts connects the feedline to the
balun, while the other set of contacts shunts the
line and goes to a tunable L match for 80/160 operation?

3: I can't see how you can use two feedlines without somesort of switching
relay in the mix, the two balanced feeders do have
to be shunted for 80/160?

Regarding the patent: First, you need a lawyer, some sort of private
forum, and a Website to promote it.

Hi SSB

I won't be any help at all with longwires, because I have never in my 40 years as an Amateur been able to get one that worked even decently.

At one time I was in the right place at the right time and had use of an infantisimal longwire (read that as abandoned telegraph wire), it received better than any other antenna I had ever used, but TX was the pits, cutting the wire to resonance produced the best TX results with very little sacrifice in the RX.

Currently my very best antenna for 160 meters is a Linear Loaded Inverted Vee, which fits in the depth of my backyard of 40 feet. This may not be the best antenna for your location though!

Antenna's are wierd birds to say the least, what seems to work the best for one ham, fails miserably for another ham. I had a loop skywire that worked great, it was originally installed as a temporary antenna, but I was pleased with it's performance, took it down, beefed it up and installed it permanently, then it didn't work worth a hoot, took it back down looking for something wrong, put it back up in the exact same place, worked fine ever since. No reason was ever found for it not working when it was first put up as the beefed up model.

Peter- while not an especially low cost solution, I use an SGC-230 automatic tuner at the base of my inverted L, which I use on 30, 40, 80, 160 meters. The 230s are often available at a good price on ebay or rec.radio.amateur.swap. Here are the pros and cons of that approach:

Pros:
1. Nearly flat SWR at the station end of the line with no manual tuning required
2. Wide excursions across the band does not require manual retuning

Cons:
1. You're limited to 200 watts by the tuner ratings
2. You need to run a control cable to the tuner (I use 8 conductor rotor cable for the SGC-230 Smart Pro)
3. The 230 must be used at the antenna feedpoint - no transmission line

There's at least one other automatic tuner - can't recall the name, but it's quite a bit cheaper and can apparently handle a transmission line to the antenna. I've used all sorts of relay switching schemes over the years with inverted L antennas, but find the automatic tuner route more desirable.

>
Yes, installing an antenna underground will have a "sigfnificant effect on
it's performance". ???! Very long traveling wave antennas like Beverages
are installed close to the ground but are very directional and inefficient.

>
>
> Any help will be greatly appreciated. Many thanks in advance.
>
> 73's

>
My current "shack" is located at one of my brother's home which is a large
property loaded with tall old trees. I used a bow & arrow to launch
somewhere around 475 feet of #14 THHN insulated stranded wire through
seven of those trees. That's a little short of a wavelength on 160. Average
height is probably 40 feet. The wire is not in a straight line, it meanders
around the property in a large C-shaped 90 dgree arc. Give or take.
>
On the ground side I tapped into the lightning rod cable and also ran a
random (150 feet?) piece of the antenna wire on the ground from the "shack"
(card table in the second-floor guest room) along a fenceline assuming it
would serve as a counterpoise.
>
Could probably win the "The Least Engineered Antenna of 1999" award.
>
I have no idea what the feedpoint impedances of the wire are on the various
bands even though I have an MFJ-259 antenna analyzer and could meassure the
input imednaces. Pointless exercise. Previous experiences with similar
end-fed random wires clearly indicatd that it doesn't matter what the swr
at the end of the wire might be, I wasn't gonna get it on the air without a

wide-range tuner.
>
So I connected the wire to my roller-inductor tuner, got the xcvr up and running and operated on all bands 160-15m including the WARC bands and was easily able to get dead flat 1:1 matches on all freqs. Ten was dead every time I happened to check that band or I'd have tried ten, too.
>
I also put up a textbook 20m coax-fed dipole, the bottom end is about five feet off the ground. The wire spanks the dipole by at least an s-unit on 20 plus the dipole picks up a lot more noise than the horizontal wire does.
>
To make a long story short I worked around 50 countries with the thing over the weekend I put it up. Lord only knows what the "patterns" might be on the various bands. If I can hear 'em I can consistently work 'em and I can hear everything the guys with beams hear. The antenna itself cost me less than $20 for the wire at Home Depot.
>
My advice being don't even think about trying to duck around the need for a decent tuner via "balun tricks" and such.

Last year someone on the net was selling the SC-518 multiband military dipole. I purchased one and need another to carry on my boat as an emergency spare. Does anyone know who was doing this? I have lost all of my records of this!

Just remember, guy, that no matter where you go, and in what hobby, people are still people and you'll meet some of every kind. The likes of William Hagen aren't unique to ham radio, I have found that no matter what hobby I look into I find a few of his kind (negative, sour, counter-productive); I am also into bodybuilding, racquetball and mountain biking. In each of those hobbies I find the very intelligent along with the very bombastic and stupid, ala' William Hagen.

You mentioned that it wasn't like "the good old days". Just remember, in the "good old days" there was no internet, with easy and quick access to so many people. No newspaper, newsletter or other means of communication has made the passing of ideas and information to SO many people. Thus, more assholes will get thier meaningless gibberish to you.

Anyway, don't worry, there are plenty of good ole boys in the hobby, many of which will be more than willing to help you out as they have done me.

Andrew:

Right now I'm running a Wilson Trucker 2000 clamped on the rail outside my basement apartment. It's close enough to a dummy load, except for the SWR.

All these suggestions (except for the first, of course. It's an apartment, for pete's sake. I need to keep this nearly invisible) have been good, and given me food for thought...

As soon as my check comes in next month, I think I'll spend some of my "fun" mondy on the antenna handbook, but you're all not going to get rid of me just 'cause I have it. ::grin::

667. What's my Antenna Problem???

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 00:00:00 UTC
From: rattlehead@my-deja.com
Message-ID: <8nos8u$l1a$1@nnrp1.deja.com>
Source record: 182146

I just recently re-tuned by 75 meter quarter wave sloper to work on a higher part of 75 meters (from about 3675 to about 3900). I did this with the aid of an MFJ antenna analyzer. Everything went fine with the usual "tune, cut and shorten the antenna, and retune" recipie. Then I hooked the coax back into my 2-position antenna switch box and all was working well.

then I plugged up my other HF antenna (a half wave 10 meter vertical) back into the other position of the antenna swtchbox, and this action alone made the resonant frequency of my sloper drop by about 90 to 100 kc's (from 3900 to about 3810 or so). when I unscrew the vertical's coax out of the 2-pos switch box, the resonant frequency of the sloper climbs back from 3810 back up to 3900.

one friend suggested that maybe my sloper isn't grounded well enough (the tower/pole a slower is mounted to is suppose to act, itself, as the counterpoise of the antenna). I would like the thoughts of everybody else out there.

My half wave vertical is an antron-99, and a couple of feet below the place it is mounted to is where I have the top of the 75/80 meter sloper mounted. Both coaxs run along side one another down the mast and tower to my station, for further information.

Source record: 182147

The other thing that works is a rod or whip with a FET follower with some band limiting impedances on the input and output. This works if there are no strong fields from nearby broadcast stations, otherwise the filtering becomes more critical. There were a number of LORAN and OMEGA antennas which were made this way, if you could turn up one of those. HP made one of the large loops for one of their VLF systems years back, but I have no recollection of the model number. I mention it since it validates the loop approach as viable.

You have read the nomenclature incorrectly. It is not a DC capacitor. It is 155-189 mfd @ 50 WVAC. Important difference, and the reason they are hard to find. Grainger, or any Air Conditioning or Motor supplier will have a suitable, but likely physically larger, and probably higher voltage rating replacement.

>
> ???????
The force from the top guy, although considerably more than the bottom set,
is
mostly vertical and wind load is quite small at present.

If I move the top two tier of guys to the concrete the mast gets very little
load beyond the guy tension which is 400# for the bottom two sets.

>
> The 1/4 inch EHS alone is rated at 6600 lbs, and that force would be
> applied at the top of the tall skinny cylinder used to support the guy
> lines.

I'm using the equivelant Phillistrand at 6000# and pretensioned to 600#, but
if
the load ever approaches 6000 # pull on the line it will have long since
passed
the survival point for the antennas, let alone the tower, or anchors.

A 25 sq ft antenna would add 520# of "side" load with an 80 MPH wind.
That would equate to quite a pull.

I know the system as is will work as I've had one up for nearly 15 years,
but I
want to go with larger antennas and am working toward understanding how much
I
have to beef up the guy anchors, or modify them.
The biggest problem is that with such a substantial system I'm tempted to
push
the limits with bigger antennas, but have no idea as to what those limits
are
and how much the different mods will raise them.
I only know enough engineering (as I said, I'm a retired computer jockey and
project manager with a math minor) to realize I need to ask lots of
questions
about specific areas.

I do understand the mechanics involved, but don't have the background to do
the

actual figures for much of it.

>
> I'd calculate the forces at ground level in that pole. I think you'll
> be amazed at the tension on one side and the compression on the other.
>
> I'd never use a guy support like that without back-guying the mast.

Back guying is not an option, but I can front brace them even using I-beam,
or
two I-beams in an "A" frame configuration..
And as I said I can move the top level, or two upper levels to anchor at the
concrete which would probably remove the need to reinforce the posts except
for
pouring them full of concrete.

> Filling the center is OK for keeping it from kinking in, but I suspect
> the tinsel strength won't increase much. You need a mechanical
> engineer, try subscribing

The Civil engineer (for the township)came out to look over the installation,
said it looked fine and signed off, but he didn't give me any figures and I
didn't get a chance to show him what I want to use to replace the small
tri-bander.
He did remark that if that old installation, which is still standing, had
lasted
15 years, that the new one should be imortal.

BTW, almost all of the tower movement is now gone as the Phillistrand sets.
I can climb by just snapping the pole strap up the back side which produces
quite a sideways impact on the tower. And...no, at my age I can not do the
whole 100 feet that way...even if I didn't have to unhook to get around the
guys
<:-))

> "towertalk@contesting.com". The nice thing

Rattle-
Sounds like the switch box ground may be a problem- making the two
antennas "see" each other too well. (really just a stab in the dark)

Then why did you buy 6000 lb cable?

>A 25 sq ft antenna would add 520# of "side" load with an 80 MPH wind.
>That would equate to quite a pull.

Did you use the sine of the angles and calculate the load, and then
look at the stress in the guy posts at ground level?

What about shock loads?

>BTW, almost all of the tower movement is now gone as the Phillistrand sets.
>I can climb by just snapping the pole strap up the back side which produces
>quite a sideways impact on the tower. And...no, at my age I can not do the
>whole 100 feet that way...even if I didn't have to unhook to get around the
>guys
><:-))

That's because there is less sag in the guys when they are lighter, so
tension increases more rapidly as the load is moved..

It isn't because the system is stronger or safer.

My towers, especially a 300 footer with insulators every 20 feet or
so in the guy lines, "move around" becuase of the weight of the
insulators. The insulators weight causes more belly in the spans, and
that makes the load increase slower when the tower moves a given
amount.

Ohm's law is fine. You have just not paid attention to what antenna
was described.

In a small loop, current can be hundreds of amperes with 100 watts.

674. CONSUMER ALERT - Beware of Eucalypt Software - Makers of Autopost & Rocketfuel!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 00:00:00 UTC
From: Warning-Warning@viwwcx.com
Message-ID: <3AE06312FE.ulvobciu@vohpranw.edu>
Source record: 182153

Eucalypt Software - Makers of Autopost & Rocketfuel --- Ripped Me Off!!!
-
All potential buyers should be warned to steer clear of this company. They have a repeated pattern
of ripping people off and ignoring requests for support.
-
I know someone who sent in the $10 registration fee for Autopost TWICE (thinking the first one may
have gotten lost) and in both instances, never got a registered version of the program and all of his
emails were completely ignored.
-
I myself purchased Rocketfuel on-line and had to pull teeth to get an unlock code. The web site was very
quick to take my money, but no registration/unlock code came for days and days. I repeatedly emailed them,
only to receive nothing but autoresponses. After 5 days I sent them a message stating that if I did not have
a working version of the program by the close of business that day, that I would challenge the credit card
charge. Magically, the code arrived several hours later.
-
What kind of way to do business is that?
-
In any case, its academic... there are other products available for free that do virtually the same thing
and I only wish that I had known about them before I wasted my time with Eucalypt Software.
-
If your in need of automatic news posting software, there is nothing better than "NNTP Power Post 2000".
It's graciously been made available free from the following web site:
-
http://net-toys.8k.com/
-
Save your money... your time... and the aggravation!
-
Peace,
-
PPN
-
-
PS: I have no affiliation with the makers of PowerPost 2000.
-

What kind?

You use the balun on the coaxial line feeding the ladder line. If you
make a 1/2 wl inverted Vee dipole and use a 1/2 wl line, you'll be
able to directly feed the ladder line. You can trim the ladder line
for lowest SWR on 40 meters.

>2: The relay is a DPDT, one set of contacts connects the feedline to the
>balun, while the other set of contacts shunts the
>line and goes to a tunable L match for 80/160 operation?

You tie the ladder line feedline together and feed the thing as a T on
160 and 80. You have to transfer the center of the feedline (it can
always be grounded) through an L network to the terminals of the T.

That's pretty easy. The shield always stays at ground. The choke
balun, if it is good enough, can even be part of the matching system.

>3: I can't see how you can use two feedlines without somesort of switching
>relay in the mix, the two balanced feeders do have
>to be shunted for 80/160?

You can use two terminals to feed the thing. I should patent this, so
I can threaten people and get some status. But I prefer to be helpful
instead.

You should write an article on this and publish it. I'd be happy to
help, but I don't want any of the credit. It means nothing to me,
because I really feel OK about myself.

>Dash remains 3 times the dot length.

The weight is the ration on on time periods to off time period. One
time period makes a dot, three periods make a dash.

So the ratio of "transmit time" to "off time" changes, but the ratio
of dot length to dash length remains contant.

In early keyers, that was accomplished by changing the threshold
point of a triangle wave triggering system.

ICOM changes the ratio of dots to dash, which is totally useless, No
CW operator in his right mind uses anything but a 1:3 ratio between
dot and dash.

It is the 1:3 to X ratio that should change with weight control. Less
weight is desirable at high speeds when the BW of the signal
approaches the BW of the filters, and more weight is better at slow
speeds especially with weak signals.

Wayne,

Remember you must force an equal amount of current into the ground or
counterpoise in any marconi antenna.

20 feet is a long ground lead, and a power line crond is definately
not a good idea.

How much ground you need is a question that would fill the chapter of
a book. But you will certainly need more than you are planning on.

>(the tower/pole a slower is mounted to is suppose to act, itself, as
>the counterpoise of the antenna). I would like the thoughts of everybody
>else out there.

Your friend is correct. Sloppers depend heavily on the tower as
something to "push against". The tower forms the other leg of a
dipole, and has just as much currenty in it as the slopper does,
assuming you don't have current flowing down other wires.

When you connect the shield of the other cable, you are changing the
path length to ground. Fixing this problem can be a real pain. You'd
need to bring all the cables down to ground and ground them securely
to a good ground before heading into the house with them. You might
also get away with choke baluns on all the other cables.

Sloppers really are mostly "blind luck" antennas. If your system
happens to work out to present a low impedance on the tower at the
mounting poiint of the slopper, they work OK. If not, you are
"screwed".

Hi, Jason:

I made a loop that tuned as low as 80M by forming around 20 pieces of #12 copper wire, each 27 ft long, into a polygon approaching a circle. I brass-bolted opposite ends of each wire to a capacitor formed by 2 brass plates about 2ft square.

I fed the thing with a link experimentally-determined to be a piece of #12 wire about 5ft long, centered opposite the capacitor, in a rectangular shape inside the main loop.

The supports were of white PVC tubing -- you create a shape that suits you.

All the stuff came either from hardware stores, electrical-supply houses, or plumbing-supply houses.

You can use small wire clamps to attach the coax to the ends of the link.

Now come the warnings:

This thing can be analyzed as a series-resonant circuit, and the only thing that limits the current in a series-resonant ckt is the operating-frequency-resistance of the components, and, in this case, the radiation-resistance of the loop. For the antenna to be efficient, this o-f-r has to be low, because, in the scheme of things, the rad-res of such a small antenna is already quite low. To get an idea of how low, with 100W, 100 A or more will flow in a well-designed loop. It flows through the reactances of the capacitor and the loop/inductor. It will take maybe 1200pF to tune this thing to 3.5 MHz, which capacitance has a reactance of -j30 ohms. Multiplying 100A by 30-ohms, we get 30KV (WARNING!) across the plates of the capacitor. Now, you can see why large plate size and wide spacing is a requirement, as well as low-loss supports for the plates.

If your eyes are not glazed over yet, you tune this beast to resonance by varying the spacing and overlap of the plates, and for usable VSWR by fiddling with the size, shape, and placement of the link. If you're interested in fine-tuning, get a slab of good dielectric material and insert it between the plates. I used teflon, plate glass, polystyrene.

Another warning: resonance isn't easy to find, cuz the Q of the thing is REALLY high, if built properly.

Your patience and perseverance WILL be tested.

Look at it this way: you didn't have to solder a thing!

Seriously, GL, and gimme a shout for additional consulting, if you wish.

Been there too (sat down from about 40ft) and *was* seriously injured -
lucky to be alive and lucky to be walking. Looking back, I'm also very
lucky not to have been left with a matching set of psychological scars.

If a bad experience does triggers something psychological, that's
certainly not a matter for personal guilt or blame. As you say, there's
not a thing the conscious mind can do to avoid it. (There are some
effective ways to get out from under this stuff, but those are outside
the scope of these rec.radio.amateur NGs.)

[...]

>simply from lack of knowledge of the device and can learn it's safe
>operation, or it could be a real instilled FEAR that may prevent him
>from ever handling a soldering iron.
>
From the original posting, it seemed specifically like fear of the
unknown:

>>I should note that I don't want to buy a soldering iron (due to the
>>fact it is a fire hazard and I don't have a workshop), drill, hacksaw,
>>or other dangerous equipment. Also, I have NO experience in
>>homebrewing amateur radio equipment.

However, he does feel confident enough to set about using a hammer, screwdriver and socket wrenches, so that's a good sign and something to build on.

I think the way to approach this particular fear is by offering gentle but *positive* encouragement - in this case, to find someone to introduce him to those tools he hasn't yet met, and show him how to use them safely.

Tom, you will be happy to know that Kachina got it right!

The weight control alters the ratio between dot length and dot+space length. There is also a "dynamics" control which sets the slope of the leading and trailing edge of the keyed waveform.

I haven't gotten into the details yet, but the Kachina "S meter" provides a choice of scales in dbm (from 0 to -124), microvolts, and "S" units. The scales are quite linear on the display and seem to make sense compared with received signals as seen on the nearby IC-765 receiver.

Remarkable radio - and the dot:dash ratio remains at 1:3 at all other settings of the keyer.

That's a good idea. I will start a company, and patent it, and post enough
teasers in
newsgroups with the hopes someone will come along and explain it to me.
Maybe we will
start a Webpage. Off course, once I publish it Tom, I will be forced to
admit you stole the idea from
me twenty years ago.

I'll take one more stab at it... You are suggesting using a coaxial choke
1:1 balun between the balanced
line and the coaxial feed. The coax end of the balun braid is grounded.

The coaxial choke is also used as the shunt inductance for the L match on 80
and 160--easily done since
it's braid is already at ground potential.

The only thing that need be "switched" is shunting the balanced feeds
together, and connecting the series capacitance
to the L network when going from 40 meters to 160 or 80.

The only remaining question is if one value of L will provide a proper match
for bands where the antenna is used as a T. I
suppose changing L values is as simple as grounding a "Tap" placed on the

coaxial winding shield at the proper inductance..

Forever lost in space...

William F. Hagen may have thought he was being wise when he
wrote what he did, but there are some very serious people who
have spent time investigating buried antennas. Contact the
ARRL and get hold of the Antenna Compendium Vol. 1. There's
an article in it entitled Subsurface Antennas and the Amateur
by Richard Silberstein, W0YBF. Even if you never put an
antenna on the ground, or close to it, Silberstein's article
should provoke some thought.

The lug on the back of the set is more for electrical safety ground. If you
want to isolate RF
consider winding a shunt balun using the coax before it enters the house
along withconnecting your coax shield and
the lightning arrestor directly to a decent ground rod outside of the house,
before entering, will help with both RF and
lightning protection. The ground rod should be immediately after your
coaxial balun.

Bringing the coax to the rig, and then trying to "ground" your station for
RF or lightning using 20 feet of wire is futile, at
best due to the inductance of the ground wire..

I use some old RG-8 coax as a ground conductor to my ground rod. I soldered two .01 pF 2KV capacitors available from radio shack one on each end of the coax. This runs from the ground buss bar on my desk to the ground rod 10 feet away. The center of the coax connects to the ground connections. This works for me with no RF problems. I did have RF problems with just a heavy gage wire run the 10 feet to the ground rod. this works for some stations and not others. You could also install A counterpoise system if you have RF problems. Connect 1/4 wave wires for each band to the ground connection point at the equipment. I used a switch to select the 1/4 wave wire for the band I was operating on. I tryed simply attaching all the wires to the same point but had RF problems on some bands and added the switch and that solved that problem. Radio Shack has a rotary switch that will work fine if you have problems simply connectiong all the 1/4 wave wires to the same point.

As I see it, the best course for Amateurs is, at this point in the "evolution" of neighborhoods and CC&Rs is simply to avoid neighborhoods where these invasive covenants exist. That's exactly what I did when I bought my current house in 1986. Avoiding these things was heavily on my mind when I bought in an older neighborhood. My house was built in 1956. In addition to avoidance of restrictions, I got a much BETTER constructed house, REAL plaster walls, brick, and a full unfinished basement that had great potential for expansion--which I have already done. I got fireplaces on the main floor, and one in the basement in which I installed a Craft wood insert. And, of course, I got a really nice corner of the basement near a huge picture window for my radio shack. And, again, NO restrictions. I have a 60' tower with an 11 element 2 meter beam, an AV8 HF vertical, an Antron 99 10 meter vertical, as well as several dipoles strung in my trees. I don't bother my neighbors, they don't "bug" me about my radios, and are very helpful and friendly--one of which even let me tie a dipole to one of his trees on the property line. So I have no problems.

Best way to keep those blue-haired ladies with the peep-over glasses from telling you what you can do with your own property is to tell 'em to stuff it, and buy some where else in an older neighborhood.

Jerry

Mr Hagen,

That smart aleck reply was totally out of line and uncalled for. SSB merely asked a question, and you reply with a worthless blast of crap. Like another person replied, if you are mad because the requirements are less than "way back when" you "worked" so hard to get your license, then get over it, get a life, or get OUT of the newsgroups. TOUGH! It is the way it IS! Hey, I was licensed under harder criteria, so what? It's people like you with an attitude who would have the hobby DIE rather than allow new people the same "knowledge" you have, or the same privileges. YOU were once a newbie, I was once a newbie, etc. Or can you even remember back that far, ya old goat? So if you've not got better things to say to people who ask questions, just put on one of those stupid "old fart" caps--you know, the ones with the bill snapped down in front--, get in your 4-door Oldsmobile, and poke slowly down to Hardees to have coffee with your other old fart buddies, and talk about how the world and Amateur Radio is going to hell in a hand basket. And you know what? It still won't change a thing!!!!! GRRRRRR!

Sorry guys,(other than Hagen) this one got to me!

Can anyone tell how the Yaesu 1000SDX rotor compares to a Ham IV? As good, better? Are the mounting holes the same?

And advice is appreciated

The best way to handle an antenna like this is to dig a hole as deep as the antenna is long, say 10 wavelengths at the 160 meter band. Bury the wire as a vertical longwire. There will be low swr and max power transfer to the antenna.

Also, plastic kids; if either don't turn out like
you expected
you can always run them back through the machine.
BUT,
don't complain if you don't have some one to clean
up after
you, cook for you, help balance the budget so you
can find
the extra money to buy that next piece of equip.
etc. etc...
Try drilling a hole in the edge of several of the
scrape MSN,
AOL, etc.,etc. disk you get in the snail mail and
tying them
on the wire with fishing line. They don't case
much wind
loading, dampen vibrations in the line. Works for
me!
P.S. Watch what you wish for, you may get it!

Set'em up Joe,
Well, congratulations! Playing with antennas is fun, so
try a few others, or just a few different things with what you
have now.
Don't think I'd bother about a tuner, but, won't hurt to
try one and see what happens.
Good luck....

So you're proposing I dig a 1600 meter deep hole for a 10 & 11 meter longwire? Jaright. What brings this kind of post on? Thinks like this really turn people off to making their own antennae, and to wanting to study hard, overcome slight dyslexia, and become a licensed Amateur operator.

Any serious suggestions/answers out there?

>

...and yet it doesn't seem to help.

These are the results for the new IC-756PRO, taken from an RSGB lab review (values below S9 are averages of measurements taken every 2 S-points):

S1-S3 1.9dB
S3-S5 2.6dB
S5-S7 2.5dB
S7-S9 2.4dB
S9 - S9+20 13.0dB
+20 - +40 22.1dB
+40 - +60 17.9dB

Don't take the figures behind the decimal point too seriously, but the message is clear enough. Whatever the other merits of the IC-756PRO receiver, the S-meter is hopeless as a means of measuring anything. But it does have a "lively" S-meter, so that's OK.

Tracking this problem through previous generations of Japanese rigs, there was a brief time when the difference between S9 and S9+20 was actually pretty close to 20dB. Now it seems even that has gone.

This is a lost cause - it's time to shrug our shoulders and get over it.

That's very good advice. Jason, you're being over-timid about what you can do safely with a soldering iron and hand tools. The greatest danger is that you'll back yourself into a corner where you can get very little satisfaction out of amateur radio.

To get a more realistic picture of what you really *can* do - even from an apartment - follow George's advice. Better still, seek out a radio club and meet *several* hams!

Forgive me, Gary, but you're missing the point of this particular thread. It isn't about how a resourceful, experienced ham can build a whole antenna farm using kitchen scissors... most of us know that, and could do it .

It's about helping a hesitant newcomer to realize that he *can* safely use normal electronics hand tools in an apartment - and especially a soldering iron.

???????

The 1/4 inch EHS alone is rated at 6600 lbs, and that force would be
applied at the top of the tall skinny cylinder used to support the guy
lines.

I'd calculate the forces at ground level in that pole. I think you'll
be amazed at the tension on one side and the compression on the other.

I'd never use a guy support like that without back-guying the mast.
Filling the center is OK for keeping it from kinking in, but I suspect
the tinsel strength won't increase much. You need a mechanical
engineer, try subscribing "towertalk@contesting.com". The nice thing
about that group is you-know-who is banned (or was a year ago), so the
F word is never used and you don't need filters.

Actually he asked if he could build a small transmitting loop like in
the Handbook without soldering, by only using hand tools.

That idea is impractical, because of the high currents in the loop he
described. He would need to use aluminum and heliarc, or copper pipe
and (yuk) solder, R rad is extremely low in that antenna. Even
conventional capaciators will fail.

If the feeder is 1/2 wl long on 40, you only need to use a choke
balun. You can the use an L network for 80 and 160.

A single relay will switch the system, or you can use two feedlines.

This idea is patent pending and I'll sue....oh never mind.

It IS possible to build a loop without a soldering iron. As I see it, the only time when you need one is when you connect the capacitor required for the fine tuning part of it.

But why be afraid of using soldering iron? It is NOT dangerous at all. The thing that may be "dangerous" (?) is to inhale the led smoke while working with it. I think this discussion has gone a bit too far. What might be even more dangerous is all the different radio equipment you may come across while being in the hobby of SWL or Ham radio (or both). Common sense works very well in all cases and also - "what you haven't tried can't be dangerous before you have discovered how easy it actually was".

Can anyone suggest an antenna that I could use to feed my spectrum analyser for monitoring between about 50 kHz and 200 kHz. It needs to roughly match the 50 ohm input and be broadband over that range. I had considered a large sinle turn shielded loop fed directly with coax (no capacitors), or a small winding on a large ferrite rod. Any suggestions?
Richard.

The point here is a *relative* indication of field strength. So mounting the "antenna" for the meter outside is not going to yield any new information, except perhaps if it could be installed outside the induction field of the transmitting antenna. Relative values will remain the same.

The problem with antennas for 80/75 is implicit in the shorthand. Its the only ham band that is espressed in this schizophrenic way. The change of 500 kc represents a change of almost 15 percent. That same change on 10 meters is only about 1.5 percent. This is why 80/75 antennas are so tricky to tune and so inherently narrowbanded. Find a design that works as well on 3500 as it does on 4000, tuner or no, and you have a real patent on your hands. With a 40 uH roller inductor and a pair of 750 pF caps, I doubt anything I could do with the tuner would help. Longer wires higher in the air would help.

Ian, with a lab-measured range of only 62 dB between no indicated signal and receiver overload point, either the receiver under test was stone deaf to signals which would blast through an ordinary receiver well above the band noise, or the RSGB lab is too incompetent to undertake such trials. There's at least 40 dB missing from somewhere.

If the lab reported very little wrong with the receiver then the latter explanation best fits the circumstances.

Reg.

Hi Joe,
Sounds like a lot of fun.

> In fact, my only initial complaint is that sometimes it seems too
> strong. Once or twice I wished I could turn down the gain even further.
>Also, LW is useless now; so much AM BCB imaging it sounds like a car radio

Joe do a search of IRCA, NRC, or NASWA they will have plans on how to
build a preselector and an attenuator.They will help get rid of the other
garbage
your radio is giving you. For LW there is a LW association, but I don't
know what it's called. You are covering such a wide frequency range, you
might
make this three preselector projects, SW, MW,LW.

Here's the NRC publications URL http://www.nrcdxas.org/catalog/
and the IRCA URL http://www.geocities.com/Heartland/5792/index1.html

Dear Reg,

If you measured some actual S meter's, you'd find they do not start
moving at noise floor.

I was working on a transceiver just yesterday, measuring the receiver.

While the receiver could hear a CW signal at -140 dBm, the S meter did
not budge until -110 dBm or so.

Hope this helps.

My commentary on your dilemma focuses not on the legal arcana of the situation, but on you househunting technique. I don't know where you are shopping, but CC&Rs are mostly a problem in new developments and subdivisions. I haven't heard many complaints from new owners of houses built before 1980. In the Phoenix area, the housing market is booming, and CC&Rs are the norm. Personally, I find most new home construction ugly, dull, vulgar, and of cheap quality. I drive by a development that sports a billboard that touts prices "from the $180's" for the most shoddy 2x4, plywood, and stucco material. No thanks! I am moving to Seattle at the end of the year, and hope to be in the home shopping mode withing 2 or 3 years after that, and from my preliminary research, CC&Rs will not be a problem. Bear in mind that I am looking at old neighborhoods in the city--not subdivisions in the 'burbs. Clapboard and brick, none of that slapdash house of cards construction for me! I can't imagine buying anything newer than about 1950, and the older the better. There are a few newer houses that are individual, interesting, and well constructed, but not many that aren't "little boxes on the hillside made of ticky-tacky."

As long as people refuse to be good neighbors, which means not only mowing your lawn and not blaring the stereo at 1 a.m., but also means showing some tolerance of difference and individuality, even where that individuality expresses a taste you do not share, until then we will continue to see this trend of CC&Rs progress. Ultimately, we hams will find a way to get out. What is frightening is that CC&Rs are getting more and more invasive and meddlesome, dictating not only what your house looks like from the outside, but the inside as well, and even your lifestyle, friends, past times, religion and politics. Sun City here in AZ was the first "community" to do this, back in the late 1950's, restricting residents' ages. Other developments have insidiously worded deed restrictions that speak indirectly to what a resident can do in his backyard, who can visit and when, who can live there (no children, no same-sex couples, no ummarried heterosexual couples, etc.), a whole litany of behavioral offenses (one that I know of in Florida even banning people wearing bikinis on their own property; many ban playing of musical instruments or outdoor use of power tools). What's next? Republicans-only? No yellow cars? No writers? [they work at home, tsk tsk!]) Where can it end? Who knows, but if there is any justice or common sense left in the world there is a great big backlash coming, led by legions fed up with being prisoners in their own homes, unable to pursue their daily lives.

I'd feed the thing with 1/2 wl of ladder line on 40. Then you can do
whatever you like in a box out at the antennas base.

That's what I did on my restricted lot, before I moved.

716. 59 MHz dual dipole help

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 00:28:25 UTC

Source record: 182171

I want to build a 59 MHz dual dipole antenna for solar radio astronomy purposes and have a bunch of questions.

Can anyone help me with the dimensions in feet and inches please?

1. What is the correct spacing distance between the two dipoles?

2. What is the correct length for the coax pieces (RG-58) from each di ole to the center feedline union? (I am not sure of the velocity facto of this Radio Shack coax.)

3. Is the length of feedline from the dipole union
into the radio a critical measurement?

4. What is an acceptable height above the ground?

5. Are ferrite toroids necessary for an antenna like this?

Thanks for any help.

Hey chirpster let the Colonel know about a new product the Fractal Fryer guaranteed to fry chicken with excess rf absorbed into the ground.
Initial test have shown a remarkable decrease in cooking time by placing the chicken under the fractal fryer. The preliminary tests show the rf going to the ground of course after nuking the bird and due to its low profile many birds can be done simultaneously.
This could be an advantage for third world countries and as always patent applied for and any slander about the fryer will be dealt swiftly and harshly by my lackeys in the legal department. <g>

Wayne,

If it is a RF ground you are seeking then a ground rod is a poor
choice. Let along a single one.....

Suggest you do a search in Deja View on the subject... You'll find
many bit of good information there.

Going back to my original post...., or the one after it, or one some where in there... I mentioned reinforcing and pouring. Either rerod and concrete, or more likely I-beam and pouring, and moving at least the top tier of guys down to the concrete.

As I recall the bending moment is around 4500#
But will drop to about half that with the top two tier being moved to the concrete.

722. Project Skywire: Preliminary Report = WOW!!!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-20 02:53:58 UTC
From: cathexis@erols.com
Message-ID: <399f3900.79916057@news.erols.com>
Source record: 182177

Greetings,

First of all, Big THX to all who replied regardless of
your views on horizontal loops. I don't have the knowledge
or experience to debate tech. with you but I would like to
share some preliminary results (very preliminary).

The idea was to try replacing a 66ft. random wire
with *something* like the "Loop Skywire" proj. as per A.R.R.L.
Hndbnk. Intended usage is for recieve only. Terminus is a RS
DX-392 which accepts any antenna as long as you can squeeze
it into a simple phono plug jack. No separate GND. jack is offered.
Proper GND for the antenna would mean disconnect ant. after use
and hook to more proper ground rod,etc. The phono jack leaves
you with a gnd wire you either hook to external gnd or let dangle.
Posi. pole of course plugs into radio. At least, that's my understanding.

The "Loop" was hardly a loop. Basically, it's wire only(no insulators)
thrown up through 4 trees and crossing my roof twice (close, but no contact).
The geometry is more like a trapazoid. The following measurements are approx.
Perimeter: 220ft. Base: 90ft.; Then 60/66/40 on around. Yes. I know, numbers
don't exactly add up. Finished at twilight so some wire I could no longer see.
Anyway, pretty close to half way betw'n 1wavelength 40M vs. 80M. This was
close to what I wanted. Perhaps even worse to you purists: First thing I
discoverd about slingshoting wire into trees?? Altitude varies hugely from tree
to tree in terms of what branches are "do-able". So therefore this loop is
slightly folded vertically as well. North and South it goes down to 20ft/25ft.
East it rises to 30 ft. West it goes at least to 50+ feet.

Hook up?? Not much. It was dark by then. Still, I had to know, Dud
or not? With 15 to 20 ft. of ends dragging on the ground, I just stripped the
ends without trimming and twisted (no solder, not even elec. tape) it onto
my phono plug leads. Bare wire leads left lying on the carport. Sloppy as heck.

Results? OUTSTANDING ! To be honest, I've no idea what the prop.
report is for today; I've been too busy to check. Weather is good here: Cool and
clear. Moderate clouds, temp 68F. But man what a sound! First of all Radio
Kuwait. Before: Max. Gain, Half volume for easy listening. Tonite MINIMUM gain
and low vol. and it's booming. The "strength indicator" on the DX-392 goes from
S-1 to S-7 (just a led display folks). Radio Kuwait was at S-5 on min. gain. A
ham from Brazil on 40M was "S-3" on min. gain, half vol. for easy listening.
Same thing for a ham from Riverside, CA. on 20M. Radio Sweden 13675 (I think)
S-5 and booming, same thing. Finally heard some reasonably clear QSO's on
80M. 'Bout time. How would a anenna. tuner help??

In fact, my only initial complaint is that sometimes it seems too strong. That is, signals before which were fainter were without competition. Now it seems like there *may* be more RFI from nearby (freq.-wise) stations bleeding into other stations.Like you'd gone from narrow-band to wide band tuning. Once or twice I wished I could turn down the gain even further. Also, LW is useless now; so much AM BCB imaging it sounds like a car radio. Is it a true loop? Or just a longer, higher random wire? Whatever it is I'm seeing big initial gains and am heading right back out there after this post to see just what else it might give me. I'n gonna DX tonite!

Sincere thx. to you all,

Andrew
KG4JBM

I'll post more when I know more. Your feedback is welcome and wished for.

Hi Jason

Back when I lived in an apartment, I had a loop in every room, some that even encircled the perimeter of the whole apartment.
All of them were totally invisible, even to the eagle eye of the landlord.

Even nicer, they didn't require a single tool, other than a scissors and you could have done without that too!

All I did was put up copper self adhesive foil under the ceiling on the wall. I used copper so I could solder the coax to it easier, but you could use aluminum tape and a small screw to affix the coax.
Once it was taped up, I just painted over it and it became invisible.
I ran the coax down the corner bead and covered it with caulk and tucked the rest under the baseboard behind the carpet tack strip to the shack.

I did drill holes in the walls and in some cases cut a groove in the corner to hide the coax under the drywall corner then retaped and jointed the corner back to square for the perimeter run.

posts.

I do have experience with concrete alone being quite elastic.
You mention using concrete well tamped in. I'm assuming you mean poured in
the semi liquid state and tamped with a vibrator? (and a fairly rich mix
using pea gravel as the largest stone?)

> Combination of concrete with an I beam does provide a series of other
problems,

This is one thing that I've not worked with before.
If I can find an I-beam that will just fit inside it would go all the way to
the bottom of the concrete while any external welding will only go down to
the concrete.

> If the I beam alone will not do the job I would look elsewhere

The I beam can be welded to the front, inserted full length, and I can use
it as a buttress to the front, weldes in as an A-frame...

> Standard thinking is to always stay the posts as Tom mentioned but it does
> provide more clutter.

Not an option
The top two tier can be anchored at the base of the post as in a regular
instalation.

One thing I've noted is that as the Kevlar (Phillistrand) guys have time to
"set" there is less and less movement. There was very little to begin with,
but doing a lot of climbing I did notice. Compared to many, if not most ham
towers I've climbed it's rock solid. <:-))

Jason, I get the feeling that you are really not all that familiar with the operation of soldering. Perhaps you are equating it to arc welding or some equally spectacular process.

To the contrary, most soldering of electronic equipment and components is noiseless and extremely safe provided that only common sense precautions are taken. I have been "flogging solder" as we used to say for over 55 years now and cannot yet show you a single burn scar. And I started back in the days when a 100-watt iron was considered "delicate" and for small work. The big iron for the regular stuff was 250 or 350 watts and weighed a few pounds.

No, I think that you need to visit a ham or even an electronics shop and observe in person what soldering amounts to. I suspect that you will find it to be a big anti-climax to what you might be expecting.

Hang in there!

Hrm... Veracity? Don't you mean validity? Veracity doesn't mean truth, it has a wholly different meaning... I guess such an educated man as a PhD (Piled Higher and Deeper?) would know something of this sort.

Just my two cents.

I remember reading, a few years ago, about longwire antennas... I seem to remember reading how many wavelengths it took before SWR was no longer an issue, but I've forgotten where I read it, and how many waves it was. I'm considering this in lieu of the dipole which was exhaustively discussed in an earlier thread.

Does a longwire require a ground plane? How are they fed? Will I need a balun or anything of the sort to use one? Will placing one on and/or slightly under the surface of the ground affect its performance?

Any help will be greatly appreciated. Many thanks in advance.

3 new catches tonite on the Skywire:

FEBA Radio Seychelles 11885 around 0345UTC
Voice of Guyana 3289 and
Radio Botswana 7255/4820 betw'n 0315-0400

All confirmed by station ID. Note the low freqs.
on the last two. A product of the new antenna's
length I assume.

Also, heard several QSO's on 160M. Fair amount
of static, but easily understood. First time I've heard
much of anything intelligible on 160M. Lots of
contesting from 160 up to 20 at least.

Perhaps not related to the new ant., heard what I
think might've been a slew of pirates betw'n 6952
and 6955. Hard to tell as there were too many
competing stations to swear it wasn't just harmonics
from elsewhere. Still, sharp drop to noise only below
6950 or above 6956. Also, some guy, fading in and
out, was really laying into Gore (no obsenities though).
Your guess is as good as mine.

Hi Art,

The problem is, as you seem to also understand, that the test data is cluttered because so many things change.

But I have made my own measurements here a few years ago when I was optimizing my antennas for my mobile. The limiting factor, or perhaps better called the "big equalizer", is the loss resistance in the ground system offered by the vehicle.

I don't have the numbers in front of me, because the data was taken maybe six years ago or longer, but my supercab long bed F-150 truck was about 25 ohms on 160 meters, and about 10 or 15 ohms on 80. It was several ohms on 40, and only looked like a good ground above twenty meters.

Because of that, it made little sense to make coil resistance (ESR) lower than maybe 25% or so of the ground resistance. Doing so resulted only in the smallest change in FS.

Adding a capacity hat, or moving the coil up high in the system, made the largest difference. That's because the radiation resistance increases by a factor of four when the system goes from pure base loading with a uniform conductor to top loading, so efficiency when ground losses dominate increase by nearly the same amount.

Of course the hat, if large enough, allows you to move the coil to any location (as long as the strong electric field is kept away from the chassis, and not coupled directly across the coil) without changing efficiency. That's because the amount of current flowing into the hat is the bulk of current flowing into the antenna on lower bands.

Now if you move the coil up on the antenna and use a small whip, coil Q is important. But the use of large diameter wire becomes limited! That's because self-resonance of the coil approaches the operating frequency, and circulating currents in the inductor kill Q.

The higher the reactance required in the coil, the longer and smaller diameter the optimum form becomes in the coil. That general limits the guage of conductor, becuase the diameter of the coil must be large compared to the wire diameter or eddy currents and stay capacitance kills Q.

Physically larger coils with large conductors are not always better, they can actually be worse than smaller guage wire in a more optimized form.

Bigger coils, with a L/D approaching 1:1 and heavy wire are most useful when reactance is low, such as in a system with a large hat or base loading....but unfortunately the higeher Q isn't needed then because reactance is so low the a modest Q siply doesn't add too much difference in ESR of the system.

That's why, despite all the various combo's, there are no "big winners". There are only a few big losers. Almost anything you do with a lot of top loading by a hat termination will win, although a properly and painfully engineered non-hat antenna can come close to a sloppy (or well done) system with a big hat.

Andrew,

I came into this late. I've turned in a dozen AM BCB stations with problems, and some "busts" have made national press.

You peaked my interest because about a year ago I turned in a Korean AM BC station in the Meadowlands in NJ. It was mixing with a transmitter from WBBR in the Meadowlands, and coming out on 1830 kHz. The mixing was in the Korean programming stations transmitter.

The FCC got them to correct the problem, after a visit.

I'm curious where you live, and hope the transmitter is not the same one back to the same tricks. Clue me in, what city are you in?

I'll listen from here, and see what I can hear. I can hear a few milliwatts of signal on a quiet night even from a thousand miles away on 160 meters, because I have very large arrays for receiving. I'm in middle Georgia.

For an RF ground, the best connection is a very short braid or strap to a good ground such as several ground posts.

If this is not possible, as for a shack on the second floor, Make the ground connection with a wire or strap which is a half-wave long. In theory, the ground potential is repeated each half wave. For multi-band operation, use several "ground leads" in parallel, one a half wave at band one, a second a half wave at band two, and so on.

The method isn't perfect, but has worked well for me for many years and a number of installations, some using end fed antennas.

Doc,

> TR, At QRP, it ought to work.

How about at 100 watts?

>>Of course, insulators wouldn't hurt anything.

Ideally I'd just put up the insulators. But, I have some medical limitations and using the staples is much quicker and physically easier work for me. Additionally, I believe stapling would be a bit more stealthy than insulators holding the wire off the house.

Thanks,

TR

That ought to work okay. I don't think I'd try much
more than that, not that I'd worry about burning the house
down, but because of the possible RFI on stuff in the house.

I didn't know what single newsgroup to post this on; please forgive the multiple groups.

Ever since I bought the car (a 1993 GMC pickup), there was a pulse-type digital noise audible on the AM receiver which raised the noise floor by 10-20 dB. Maybe more. AM DXing was out of the question, and even in-city listening was frequently not possible or at least annoying.

A few years ago, I tried removing the antenna to clean corrosion on the ground connection to the truck body. This seemed to me to help. I would guess that I may have lowered the offending noise by 2 or 3 dB.

More troubleshooting over the years led to the discovery that the coax from the whip to the RF deck (mounted low in the dash approximately mid-cab) passed right behind the behind-the-glovebox computer. I guessed that this was the pickup mechanism, so I put several of those split ferrite cores around all of the leads in and out of the shielded CPU box. But this didn't work at all.

I left it alone for a few years, and then last month something got into me to try one more time. I located the coax coming into the RF deck, and I took all of those split ferrite cores that were doing nothing and clamped them right over the coax cable where they entered the RF deck. I was able to fit four or five of them onto the antenna cable before my fingers just ran out of room trying to reach up into the dash. This worked so well that I took a long drive just to hear what the radio was doing! The receiver was so quiet it was astonishing. AM DX is now a definite possibility.

Many of you will recognize that essentially what I did by using the split ferrite RFI suppressors is construct a kind of a W2DU balun. I posted this in the hopes that some of you suffering RFI in the car will benefit from this. Good luck!

What would be a small but decent dual or even tri band antenna for hiding in a tree? I really need one that is easy to get up in a tree and that is easily hidden (ie nothing really big). What do you recommend and have used in the past for stuff like this? I have antenna restrictions and have heard many recommendations from hams on the air but have either forgotten the model numbers or have not been able to find the antennas they are talking about. Any tips? Thanks!

KG4IVT.

Doc,

I was more concerned with the safety aspects of not using insulators at 100 watts. I've already done a lot of RFI prevention in my own house due to my 6m SSB addiction. I'm not too concerned here. Unfortunately, my neighbors are a different issue:-(

In terms of grounding, one thing you might consider is getting a 10' piece of copper pipe 1/2 or 3/4" diameter and sweating on a whatever adapters are necessary to attach a garden hose to the end and letting the force of the water act as a drill bit of sorts. There is no reason a ground rod has to be solid since it is the outer surface or "skin effect" we are concerned with. When you are done, remove the adapters and clamp a ground strap to the pipe and voila, you have a ground!

Good Luck!

Source record: 181932

A relative gave me a nice little homemade quad antenna that he used on 2m.
I have a simple question: How do I mount and orient this antenna? Should I
attach it to a rotor or is it omni-directional?
It has a short "mast" attached which appears to have been attached at a
right angle to the main mast by means of a "U-bolt" clamp.
All help is appreciated.

Actually, I believe Clinton's election proved that it took votes from the republicans... he won and entered the white house by winning less than 40 percent of the vote. And no need to speculate further what had happened if the election process on the presidential level required a runoff in that case.

>Last election I voted for the little

>on different vehicles and days.

I once set up a sort of test platform on 40 meters with an AC power supply, a standard mount, and a field strength meter read by another ham some distance away, who recorded the results without being able to see the antenna I was putting on. The outbacker came in dead last (probably because I didn't have a base loaded whip to try out at the time, but.....) At any rate, I did try Hustler resonators, a Webster Bandspanner, and even a Comet 4 band special. I also had a bird wattmeter and measured forward as well as reflected power. They were all relatively close with the best match for a Hustler resonator, but all calculated to be less than 1.2 to 1 SWR at 50 watts. Was it scientific, probably not, not enough samples, was it reproducible, yes it was. Oh and the FSM used was also calibrated with an attenuator to produce the same readings with the attenuation used to determine which antenna worked best. It was fun doing it, but it also shows how bored a ham can get living in an apartment and wanting to get on HF with the most efficient HF mobile signal.

>In the near future we will be comparing all of the above on the
>same platform results with be forthcoming some time this fall.
Good, but your results don't agree with most of mine, or those from the shootouts I've read about. Don't know if there will be one on the west coast this year, but I should note that for efficiency, large coils seem to work best on 75 meters and on 40 meters.

Further, I still have the report on a shootout in 1997 on 75 meters archived, here is the report pasted in:

From: bart@wb6hqk.ampr.org (Bart Rowlett)
To: w6kkt@frazmtn.com
SANTA BARBARA ANTENNA TRIALS - AUGUST 17, 1997

Here are the results from the 75 meter mobile antenna trials
held near Santa Barbara on August 17 1997. The callsigns and names
are self explainatory. The numbers, typically between 59.0 and 65.0 are
the measured field strength readings in dB. The field strength meter measured
the horizontal magnetic field component of the radiated signal at a distance
of approximatly 800 meters and accuratly represents the vertically polarized
(electric field) groundwave, which is proportional to the low angle skywave
radiation suitable for working DX. The measurements do not necessarily
reflect the performance of the antenna system for working short skip (NVIS)

but are generally a useful indicator of overall performance. In most cases, the measurements were done at 3995 kHz but we allowed the frequency to be lowered if required to achieve adequate power transfer. The power input to the antenna system was taken as the difference between forward and reflected power as measured with a Bird wattmeter anywhere the operator could provide feedline access, usually at the rig antenna connector. The forward power was typically between 40 and 50 watts and all readings have been normalized. The absolute value of the field strength measurements have no meaning whatsoever but the differences accuratly reflect antenna system differences. Note, for 75 meter mobile installations, the vehicle is a major part of the antenna system and the data reflects entire antenna system performance. In some cases, extensive bonding of body and frame members has been done to reduce losses and improve counterpoise effectiveness. Unless stated, all vehicles were legal to drive with in the state of California with the antenna systems deployed and presumably operable. When the field strength trial began at around 0800, there was a slight drizzle which tended to detune (down frequency) the open air bugcatcher coils by around 20 kHz. The earlier measurements made with the bugcatchers tended to be a couple of tenths of a dB below the later measurements and I believe that to be as a result of water on the coil and not a shift in antenna range calibration. In the past we have found the same equipment to be repeatable to within +- 0.15 dB or better. The comparisons can be expected to be accurate to +- 0.2 dB.

RESULTS

CAPACITY HATS: These antennas had capacity hats of some sort for top loading.

K7POF - BOB 64.8 (lST RUN) 65.1 (2ND RUN LATER IN THE DAY)
W6MMA - VERN 64.9

KK5YY - GERALD 56.4 ROOFTOP MOUNTED OUTBACKER WITH TRIPLE MAGNET MOUNT
W6RCA - CECIL 52.2 11.5' WHIP (NO COIL)

ADDITIONAL DETAILS:

CAPACITY HATS:

K7POF - CENTER-LOADED, LARGE CAPACITY HAT, WIRES TO FRONT.
W6MMA - BBS SCREWDRIVER, 5' HAT WITH 18 RADIALS, R. FRONT BUMPER.
W6RCA - HOMEBREW MID-BACK BUMPER, OVER THE VEHICLE,TOWARD FRONT.
N6BT - FORCE TWELVE PLUMBER'S DELIGHT ALL AROUND VEHICLE.
K6SDQ - CENTER-LOADED WITH 42" HAT @ 11 ABOVE COIL. LEFT REAR.
KE6DM - CENTER-LOADED MID-BACK BUMPER 17" HAT.
K6MB - LEFT, REAR MOUNT, CENTER-LOADED WITH TWO WIRES TOWARD FRONT.

BUGCATCHER:

K7POF - MASTER MOBILE, LEFT REAR, 7011 BASE, 64" WHIP.
WA6JPR - BUGCATCHER, MID-BACK BUMPER MOUNT. (NO PAPERWORK)
WB6HQK - 5.25 INCH DIA COIL ON 2.5 FOOT MAST MOUNTED ON TONNEAU COVER, 72 WHIP
K6MB - BUGCATCHER, LEFT REAR.
W6RCA - TRAILER HITCH MOUNT, 3' BASE, 6X6" COIL, 5' TOP.
W6JEO - BASE-LOADED, 2x12" COIL, 62.511 TOP, 3.5' GND TO BASE.
W5GYJ - BASE-LOADED, 8x12" COIL, 7' TOP, 3' GND TO BASE. (GLA COIL)
KC6MAJ - CENTER-LOADED, ON TRUNK, 3X5" COIL. (HUSTLER COIL)
WB6ZJA - TEXAS B.C. LEFT ABAFT CAB MOUNT, 16"-HAT 12" ABOVE COIL.

SCREWDRIVER:

W6MMA - AS ABOVE SANS HAT.
K6RCL - HIGH SIERRA 1000, CNTR-LEFT MOUNT, GMC P.U.
WA6HEY - W6AAQ ANT., REAR, LEFT MOUNT @ 43" GND TO BASE.
K7EZ - W6AAG ANT., REAR MOUNT, 36" GND TO BASE.
KA6TAY - HIGH SIERRA, CNTR REAR BUMPER MOUNT 16" GND TO BASE.

OTHER:

WA6JPR - BANDHOPPER.
WA6JPR - BANDSPANNER.
WA6JPR - STAINLESS STEEL.
KK5YY - OUTBACKER,CNTR-ROOF, MAG-MOUNT.
W6RCA - 11.5' WHIP (NO COIL) TRAILER HITCH MOUNT.

Additional Notes:

KC6MAJ and WB6ZJA apparantly had grounding problems and the results are not typical of similar installations.

These are the final results but updates may occur as additional information becomes available. If you have any additional information or errors to report, please let me know.

If you have any questions please feel free to email me: bart@wb6hqk.ampr.org

If you're on the west coast, many of those involved can often be found on 3850 kHz from 0730 to 1000 and 3995 kHz from 1700 to 1800 PDT. We would like for you to join us!

If the grounding the cable or the switch is having that much effect on
the antenna, I'd fix the real problem. Otherwise, you are likely
wasting a bunch of RF that could be going out from a useful place like
the antenna.

That's why slopers are often called sloppers, because they are sloppy
systems.

I assume you bring all the feedlines down the tower to ground level,
and then go into the house with the cable at ground level? And the
tower is grounded for RF?

There is no need to model it. With common mode currents, nothing flows
on the inside of the cable. The center conductor woiuld have no effect
at all in a mode where the cable is being used as an RF ground.

The RF reactance of those capacitors (as I recall they were .01 uF) is
a few ohms on 160 meters, and proportionally less on higher bands. The
capacitor would have little effect anyway, but in the spot they
connect them it has no effect at all on the system.

On a similar topic, has anybody tried an inverted-L with a switch at the top of the vertical section, so that the horizontal loading wire can be removed for the higher bands?

I'm looking for a method of placing a switch at the top of a 1.5-2in pole, so low weight and windload are important. Any experience of small vacuum relays in such locations, for example?

Obviously there are other solutions besides a switch, for example traps or stubs - but they can only "switch" at one frequency, so it would need several traps in series for an all-band solution (unfortunately the "lowpass" trap hasn't been invented yet).

>by a jacket.

Dow 744 seems to be the best value in a non-acetoxy, non-slump material
(at least in a country where GE products such as Silicone II aren't
available). 744 is expensive compared with regular household silicone
rubbers, but it's harder and tougher. The downside is that 744 takes at
least 24 hours to cure - and once again, it takes longer for a larger
thickness.

Another problem is that after about a year, the unused 744 in an opened
cartridge transforms itself into an ivory goo that makes a good sealant
but never sets hard at all... still useful, but not what you thought
you'd bought.

Hi Brad,
Sure this will work.... but won't changing bands be a real pain? Unless
you are operating at the feed point I can see you lowering the antenna,
changing taps and raising it again????

Why not feed a long dipole (130+ feet) with open 'ladder' line and put
a tuner in your shack???
Even a simple 'tapped' coil tuner would make 'tuning' a lost easier
when you change bands.

Just a thought..

Actually if you look at the results in shootouts, it is the large
capacitance hats that make the most difference. The larger the hat,
the less critical coil location and type becomes.

I don't know why anyone would think an antenna with most of the
loading down low would be an efficient antenna, especially when the
antenna is used in an application where ground loss resistance is
high.

I haven't paid any attention to this issue, having done as Roger advises in the part snipped (ie: avoid covenants) but before the 70's many properties were burdened by covenants forbidding selling to people of color, Jews, et al. These covenants were struck down by the courts which, in the process, weakened all covenants. In the late 1970s a Maryland CBr was thus able to win against his neighborhood assn in court because the judge, citing precidences striking covenants, ruled that the neighbors had to show that his antenna harmed them (eg, reduced their property values) to enforce their "no antenna" rule. Perhaps someone with the requsite legal skills (which I lack) could research this angle.

CW,

I've definitely identified a major source of RFI:
It's 1310 WDCT, a all Korean AM BC station. It's small,
only 5Kw I think. But it's offices are only a mile from my
house, though I haven't spotted a tower as yet. I can
definitely hear harmonics spilling over at least from
200 Khz approx. up into the 160M band. Awful!!

I think the best place to start is to find a detailed description of how a folded dipole works, especially off the center frequency. One of the better descriptions I have seen is in "Antenna Theory, Analysis and design" by Balanis, which is an upper division undergraduate level textbook. My favorite textbook on the topic is is "Fields and Waves in Communication Electronics" by Ramo, Whinnery and Van Duzer.

The ARRL publishes a paperback book titled "Antenna Impedance Matching" by Caron, which introduces the concepts of matching with combinations of stubs and lumped components. Most of the techniques are based on graphical methods utilizing the Smith Chart transmission line calculator and don't necessarily take stub dissipation losses into account. At HF frequencies, such as the 75m Bazooka, stub losses are likely to be high enough so they can not be neglected as is the usual VHF & UHF practice. A good approach to analyzing the Bazooka is to first model the antenna with a Smith Chart to get a feel for what is supposed to be happening. Then model the antenna analytically using the complete transmission line model for the stubs and see what happens.

Gotta Run....

Hi, I have a question about antennas. I have an ICOM IC-746 transceiver and I will be getting a combination 2/6/70cm antenna made by diamond antenna, and also the TITAN DX from GAP antenna. My question is about grounding them. I live in Las Vegas, Nevada and live on the side of a mountain so the ground is extremely hard. You could only dig down 6 inches with a shovel before you needed a pick. I have been told that I need to drive an 8 foot ground rod into the ground. Since going down that deep is practically impossible, I was wondering if 4 feet would be sufficient? Also, where do I attach the ground wire to on the antenna? Do I attach it to the tripods they are mounted on, to the mast next to the antenna, or somewhere on the antenna itself, or all three? Another question I have is where do I place the lightning arrestor in the coax line? Is it placed as close to the antenna as possible, or inside the house close to the transceiver? I have one last question. Since I will be using TWO antennas, I will be using two coax lines for both of the antennas. Both of the coax lines will be 100 feet long, BUT is it ok to have the coax lines right next to each other or does there need to be some separation between the coax lines as I mount them along side the house? I will only be using one antenna to transmit at a time, so I was thinking I could keep them next to each other, but if you don't think I should, please tell me. Thanks so much for taking the time to read this and answer my questions,

-Pete

Given that the usual tolerances are any where
from 5 to 20 percent [+/-] I'd try the 63pF and see
how far out of spec it puts you. Then adjust the
antenna itself to get back where you want to be.
With any luck you might get a cap that is on the
high side.

Also is there room to parallel the 63pF with a 5pF?
(or even a 5, 12 and 50). It increases the cost and
is more mechanically "fragile" but gets you closer
to factory spec.
Good luck

Pete,

I can't vouch for the ground density in your area, but here's a trick
I use here to drive ground rods. If the earth will soften up when wet,
then you can dig down a foot or so (less if too hard), and fill the hole
with water. Do this a couple times until the ground softens up enough
to drive a rod. Eight feet is the standard, but if you can't go lower,
it's better than nothing.

As an ex-broadcast engineer with a few of these a long time ago too, I have a suggestion for you. The worst case(s) of this we ever had at WTAW-AM in College Station turned out to be from a strange source. We were plagued with this big time years ago. Turns out that the neutrals in the power line grid around the station weren't quite neutral with earth ground! What with three phase this and that .. and single phase this and that and RF everywhere close to the station site... plus a 69KV primary distribution circuit that went for miles just adjacent betweeen us'n our competitor, KORA .. Oh never mind, you get the idea!

For example, about two blocks south of the transmitter site a guy wire anchoring a utility line pole went up toward the pole beside a lower level supposedly grounded utility line. They were barely touching each other, dissimilar metals at that!

Turned out that there was a solid few volts difference between these two 'grounded' lines, and over time, not only that, but there was corrosion present at the rubbing surface as well!

We cured this one by going up and wiring an egg insulator between the two lines, so they couldn't touch each other! A whole lot of folks sighed in relief over this discovery!

As you chase this one down, remember to be kind, as you can, to all concerned. Remember that at 2KW PEP, you can also wind up in the same boat from your RF up a little higher in TV land! You may be turn out to be like a large number of us that have gone before you.

You learn that rectifiers can do lots that don't rectify the situation!

Modern BC stations really aren't stuck in there with dirty output circuits. They do have some care put into the design. This that get disjointed often happen off-premises that bring the misery.

--> Sleep well; OS2's still awake! ;)

Many of today's dual band (70cm/2m) mobile antennas claim to be two 5/8's collinear on 70cm and either a single or half-wave or 5/8 wave on 2m. Many use a simple open coil in the center between the two 5/8 sections. (Some encapsulate the coil, but same difference)

As I understand the discussion, it is being stated that these antennas DO NOT work properly in collinear fashion because the phase shift is not (and cannot be made) large enough with a coil. (I'm referring to how they are sold, not by kludging in a replacement stub or center tap) This is what I have gleaned from Roy and Tom's comments.

From Roy's earlier post, it seemed that he was saying that if you try to use a coil for the required phase shift you get reduced gain and and elevated lobe (not at horizon). As I understood it, there was still gain over a single 5/8 wave, but not at what appears to be a "useful" elevation.

If this is true, it seems that a straightforward 5/8 for 70cm would likely outperform these "collinears" at the horizon. If that is true, then many of us who have serious needs for good performance on 70cm would be better off with a separate 70cm 5/8 wave and forget about the dual band "alleged" collinears that seem to be the rule of thumb these days.

Do I have this right, or have I completely jumbled this up in sifting through all these interesting posts about the "collinear conundrum" ?

780. House loop. Insulators required?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-21 00:00:00 UTC
From: TR <w7trx@mindspring.com>
Message-ID: <8nrra2$1j6$1@nntp9.atl.mindspring.net>
Source record: 182053

Greetings,

I am in the planning stages of installing a stealth loop around the perimeter of my house, under the eaves. The house has cedar siding. I plan to operate mostly QRP, but want the installation to be capable of handling 100 watts as needed. I plan to use insulated wire, closely matching the color of the house. The wire is stranded 12 awg rated for in-house AC wiring. I live near Seattle, so rain may be a factor.

I would like to staple the antenna directly to the house for maximum stealth and ease of installation. The front and rear of the house are the longest runs and are under the eaves. This allows me to staple to the 2x4s under the eaves (approx. every 18"), leaving the antenna dry and mostly suspended in the air. I would like to use a Telco type stapler, using rounded staples to attach the wire to the studs. The ends of the house have no overhang, but are generally less visible. I could probably use some sort of stand-off insulator to keep the wire off the cedar siding.

As I read about stealth antennas, some folks seem to run any sort of antenna, any place, without concern for insulators. Others recommend a 6" stand-off insulator from the house. I'm confused.

For my antenna setup, are stand-off insulators necessary for proper operation or safety?

If stand-off insulators are a good idea, what is the minimum recommended distance from the house?

Does anyone know of a source of stand-off insulator that can be directly screwed into wood? The traditional amateur radio type insulators don't lend themselves well to this application. I cannot find anything suitable from hardware or building stores either. Not sure if electric fence insulators could be adapted.

To maximize stealth, can insulators be painted? I'm guessing this will affect the insulation properties, but for my use, is this a concern?

Thanks to all for your expertise.

Hasan,

I agree, but with one modification. As Tom Bruhns has pointed out, the coils on some commerical collinears, such as cell phone antennas, are pretty long. These would be subject to coupling to the antenna elements, and the current at one end wouldn't necessarily be equal to the current at the other, as in the idealized zero-size circuits I modeled. So it's possible that the commercial collinears do work as advertised. At least, my modeling shouldn't be extended to conclude that they can't.

782. Matlab

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-21 00:00:00 UTC
From: "George , W5YR" <w5yr@att.net>
Message-ID: <39A17869.4CA69F12@att.net>
Source record: 182055

I have recently run across the Matlab program (student edition) at what appears to be a very good price - $30.

From the description, it is very similar to the Mathcad program which I have seen mentioned in postings on this NG. It is limited in matix size to a maximum of 32x32 but otherwise is fully functional as to graphing, equation solving, etc.

Does anyone have any knowledge of or experience with Matlab that they would care to share?

At $30, it is worth looking at, I know - just curious if anyone knows of it.

Hmmm ....maybe I will build a *temporary* wire directional like
many that night.
Since this character will be blasting 2000 watts Rap and Salsa music till
8:AM through old HI Z turntables and *very long* speaker wire
It would be great to invite some old hams in the area over with the big BIG
tube gear to add to the fun.
Off to look for eggs and poles...............:) :) :) :)

Assuming the switch is OK, most do not disconnect the ground side. So
the problem maybe that the other antenna is hanging, in effect, off the
gound side of your sloper .. a situation that you change when you
unscrew the connector.

>capacitance hats that make the most difference. The larger the hat,
>the less critical coil location and type becomes.

But Tom, the difference between the best whip and the best Capacity hat is only one to two dB. Yes, the difference is reproducible, but I'ld bet that putting a capacity hat sufficiently spaced above a one inch diameter wouldn't make the one inch center fed coil better than someone with a 5 inch diameter coil & whip(once again center fed). One day, someone is going to have to find a single site with perhaps an abandoned car with a properly designed mount and quick disconnect setup and try every available combination repeatedly. I do note that two to 2 1/2 inch diameter coils seem to be the breakoff point for a somewhat efficient mobile antenna on 75 meters and 40 meters.

Of course, if you've played with the things and the one inch will work well in your testing, I'll take your word over my guessing, but I did try a capacity hat over a Hustler Resonator, and note that I had to use a 30 meter coil to be able to get something a rig would feed into on 40 meters with a capacity hat. I also note that Hustler resonators aren't strong enough to take a large hat while in motion, and that they are close wound, rather than spaced like many better performing coils.

I wonder if depth helps all that much in arid soil. If you can only get down a foot or so, you might opt for a "mat" approach to spread things out over a large surface area (lotsa little rods connected in a star pattern or just a good radial system).

I live on a dry sandpile where it's real easy to drive a rod 6-8 feet (as long as you miss the rocks). But, instead of a ground rod at the station, I use a ground mat consisting of 12 1/2-wave radials under the antenna coupled (loosely) to a 125-foot well casing at the center. So far, no direct hits or blown pumps, but I feel like it keeps the action away from the house better than a 8-foot rod in the sand next to the radio. It also reduces ground-losses in the antenna and helps my signal.

Matlab is primarily aimed at matrix operations, and system simulations. Many people use it for doing DSP design work.

For my money I would try to get my hands on the student edition of Mathcad 2000 Pro. It comes with the DSP function pack, wavelet function pack, a 2D CAD drawing program, etc. The student version is EXACTLY the same as the retail Mathcad 2000 Pro version with NO program limitations, I E-mailed Mathsoft who verified this. At $100 USD it is a better deal than Matlab. Since it comes with the above function packs for free (student version), which if you had to buy the software out right, would cost over $1700 !! As a Ham Radio license holder I think Mathsoft considers this an educational use, so you may be able to order it from them direct. If not then pay a visit to your local university book store. If you do get it don't forget to stop by the Mathsoft web site to down load the most current patch file for it, which I think is version 2a currently.

I have a 'Fidelity 2000' CB radio (CB/81). Bought it at a village jumble
sale in 1984 for ï¿½15, and did the 'Bury Amateur Radio Society' mod to

convert it for 10m FM. It has the Cybernet board. Brilliant S-meter. 6dB = one S-point, S1 to S9. How do they do it? Don't know. Has AGC, which may help with 'logging' the voltage-to-meter deflection.

In comparison, my 2m Yaesu FT480 S-meter ('gooseberries, cherries, and oranges') is absolutely total rubbish.

Ian.

pete4www,
If the ground is that hard, you might think about laying
out radials instead of a ground rod. The more metal you put
down, the better the ground. If it's close, you might also
consider using the 'house' ground rod. If a ground rod is
not into the water table, it really isn't doing you any good.
Running the feed lines together shouldn't do any harm at
all. The lightning arrestor should be at the base of the
antennas, or at least outside the house. Depending on the
type of arrestor you have, you may be wasting your time.
Most common lightning arrestors are worthless, they don't
act fast enough. If it's a 'spark gap' type, throw it away.
'Doc

>Tom

I think you have it. Dot rate is constant. But the dots and dashes
extend (but keep the same ratio between each other to fill in the
spaces).

So the CW gets "heavier" and lighter with weight...hmmm...that must be
why we call it weight instead of ratio.

Hey Doc, read the opening thread again.

1.) He has a sloper.

2.) Slopers depend on the tower and anything connected to the tower
for a ground.

3.) Anything that cnages the ground will detune the sloper, such as
connecting a feedline and antenna on or near the tower to the station
ground.

4.) If the switch was bad, the RFI (from no ground) or the SWR change
(from two antennas being paralleled would be great.

5.) I'd wager if he touches the shield of the Antron antenna to the
switch or any other ground in the shack, his sloper will change
frequency.

6.) Slopers are often problems like this, because the work against the
tower and anything connected to or near the tower.

That article appeared in 73 Magazine, not QST.

It was a serious article. 73 Magazine is the source of some of the
worse possible information in the world, because they print anything
that falls on the desk.

That idea is absolute rubbish.

Actually Art field strength measurements indicate that they are on a
par with Hamsticks and Hustlers. I am VERY suspicious of owner
reports how on earth do you expect to compare one to another
on different vehicles and days.

In the near future we will be comparing all of the above on the
same platform results with be forthcoming some time this fall.

heh, well, not a convenient one, BUT, any solution that works is a good one. somebody else mentioned this possibility; could I solve the problem by just grounding the body of the switchbox itself maybe? I don't know how I could arrange it such that the unused position is re-directed to ground, without manually doing so each time; and in this case, I might as well do as you say, and just unscrew the vertical's coax.

So, how could I accomplish this? bring the coaxes all the way down the
tower to the bottom, literally, and then connect the braided shield of
the coax to a ground rod at that point via a wire? I already have a
ground rod there at that point, the the coaxes already come down to the
ground before running into the house... so this would be a simple and
quick solution.

I have an Outbacker and I like it very much. I have it installed on a 3 magnet mount which I use in the middle of the roof on my minivan and on my truck. I have no trouble working 20, 40 ,and 75. One thing I like about it is that I don't have to worry catching it on tree limbs and bridges. I keep the banana clip and sockets clean and I use silicon grease on them. The only gripe I had about the antenna is that it costs too darn much.

>In a small loop, current can be hundreds of amperes with 100 watts.

Perhaps not! Apparently they are talking about what I would call an
"Army Loop" antenna or a "Hart Loop" antenna.
When I think of "Small Transmitting Loop Antenna's" for example 2 to
17 MHz, I visualize a 20 foot diameter loop, possibly as small as 14
feet in diameter for 7 to 14 MHz.

Sorry for the confusion!

Hi Ian

Agreed!

Also, if you have any ideas, I'm game, tired of paying shrinks for nothing, or should I say, no progress.

I'm glad you recovered from your fall, sorry to hear you were injured. My fall was broken a couple of times on the way down which decreased the acceleration factor I presume. I can't really say what I felt for sure, I didn't wake up right away, but apparently I hit flat based on the bruises on my backside, which might be what saved my dumb ^$$.

Alright dudes!

I vote third party, when the opportunity arises, of course it usually steals votes from the democrats. Last election I voted for the little guy with the big ears and all the money.

However, one thing I have learned in my 53 years on this planet, when the Democrats are in, I have money left over to sock away, when the Republicans are in, I have to draw out what I socked away while the Democrats were in.

However (again) I won't give the democrats all the credit, it's the rich republicans who made the nice loopholes that the rest of us are slowly finding while the democrats are pointing them out and trying to close them back up.

Hi Joe

There may be a loophole, we found one here!

I used to have a fairly nice tower, when it came down, I couldn't put up another, but I do have a push-pole, however, it is NOT set in concrete.

Reason being, there was a little loophole that allows certain temporary installations. In this case, temporary meaning not permanently affixed. This little loophole has allowed several homeowners to install small storage sheds without slabs, provided it met with the mounting requirements for a temporary installation, which was simply four 2 foot auger type ground anchors. They never defined a length of time for a temporary installation.
I got my push-pole up under a clause that allows for a temporary supporting structure for utilities or communications wires. It clearly defined three types of mounts, the one that I fall under was temporary utility and communications poles, which gave installation parameters for regular round utility poles, 4x4 wooden posts and pipes. I installed the pipe (push-pole) as a temporary communications support, following the definitions to the letter. I also keep some construction project going on at all times (meaning there is a hole between the living room and garage this year), plus an unfinished driveway that the city is hounding me about finishing.

Where there's a will theirs relatives, I mean there's a way.

Hi
I have an small astronomical observatory 100Km North of Ottawa. In order to measure asteroid occultations, reduce orbits and time other astronomical events. I need to receive the UTC time signal. To that end. I purchased a Grundig YB400PE radio. With it. I can best receive channels CHU at 3330 and 7335. With transmitter located at about 110Km South of the observatory.
Here is the problem. When I engage the telescope control drive. The 24V pulse modulated stepper motors create an electronic clatter that completely overrides the UTC signal. So I've been thinking of running a coaxial wire to an antenna away from the observatory. When I started to investigate the subject in the net. It quickly became apparent that antenna design is a complex mater. Thus I wonder If some of you experts could provide a simple antenna design to solve this astronomer's noisy problem. Please note that although I have a decent knowledge of electronics. I am a complete neophyte when it comes to antennas.
Note: I have lots of trees around to use as mast if needed.

Thanks in advance.

I'd say that Matlab and MathCad do different, complementary things.
Matlab is very good at numberical calculations involving matrix
functions, and MathCad is good at symbolic manipulations,
presentation, and acting like a "math spreadsheet." I use both of
them; which I use at a given time depends on what I'm trying to
accomplish.

Actually, I don't use Matlab much. Instead, I use the very similar
SciLab, which is freeware. You can download it from a site in France.
It comes with some pretty decent manuals. It's not perfect, but there
are some areas that IMO it does better than Matlab.

Cheers,
Tom

No, it was about 47%. Get used to the idea, as other parties gain prominence and strength. The rest of the democratically governed world would marvel at a 47% take of the vote. We'll see Dem-Green and Rep-Reform (with the Libs split between them) Congressional parliamentary-style coalitions, or some such, within two more election cycles, I believe. Majority rule is to be feared anyway, for its potential for stifling dissent and repressing minority views and their pursuing of happiness. All tyranny begins with the approval of a majority. That's what the 'no establishment' (of religion) clause of the First Amendment is all about: keeping the majority off the backs of the minority. And "rule" by majority was certainly not the intention of *all* of the Founders, Madison among them. The reason we have the Electoral College and a Senate that is not proportional is to counterbalance the majority. I'd love to see the Electoral College done away with (as well as holding all primaries of all parties on the same day; New Hampshire doesn't vote in the *General* election 3 months before California: why do you suppose that is?), it would go along way towards making Presidential elections more equitable and "democratic." "Winner take all" is a euphemism for quashing the voice and will of regional minorities. Run-offs are held when two or more candidates are within a percent or *less* of each other, not simply when the nominal winner scores below 50%. No reason to have a run-off when Candidate A has 47% and Candidate B has 35%. As long as we are considering parliamentary-style changes to our electoral system, why not restrict election campaigns to no longer than 180 days before Election Day, instead of the current practice of 3 years 11 months. Hmmmm.

John,
I have just recently installed a HyTower and will be happy to share
information with you. The manual has fey parts details for the small parts.
Can you be more specific about your needs?

The UNloaded 11.5 foot whip antenna it did beat was a very very poor
system.

Most good antennas were around 62 dB, and some a few dB higher. 6-10
dB down may not sound like when signals are strong, but it's a huge
difference when signals are marginal.

>You can gain a bit by grounding an Outbacker and matching the load.

A large diameter has nothing to do with it. In many cases, Q is
higher with a longer smaller diameter coil of reasonable size wire.

>The most interesting thing of the lot was the stainless steel coil
>bugcatcher. It was very much a copy of the 480 coil that Henry
>Allen makes but in stainless. Guess that makes a case for
>ohmic losses and efficiency.

Ground losses swamp out changes in loss resistance in antennas. The
larger the vehicle you put the antennas on, the more the spread in
efficiency when ESR in the antenna is minimized.

The smaller the vehicle, the more important current distribution in
the antenna becomes.

Hams that think large diameter coils offer optimum performance are
missing the boat. Even a #14 wire coil can have Q of around 300 in a
mobile, and the largest coils are lucky to reach 600. When the coil
requires a large amount of reactance, a long slender coil with smaller
wire can (and usually does) have more Q that a large diameter large
conductor inductor.

All other things equal that amounts to a very small change when ground
losses are considered. With a perfect ground that would be an
efficiency change of 2, half the loss with the larger coil. When
ground losses are thrown in, the difference is meaningless.

Moving from 100% base loading to 100% top loading will change
efficiency by a factor of four.

Roger:
Hi, Just a comment, I have found that any attempt to 'seal' a
connection using silicone and or caulk led to problems with water
getting into the connection and causing lots of problems as it could
not get back out. Over time, I have found that somewhere the silicone
will leak, usually between it and another surface. Capillary action
just draws the water in!
I'd suggest two wraps of good electrical tape. I have had good luck
covering the tape with coax seal. The tape lets you get the seal off
and leaves the wire 'clean'. I have heard that coax seal will get
brittle but have not had that problem... have a number of connections
that have been in the WX for years.
If the connection is large, multiple splices etc., place them in a
plastic or metal box, sealed to the wx on top with a hole on the bottom
to allow it to 'breathe'! Bring the wires in through the bottom.
Why not consider "N" connectors for that 9913? They are water tight if
properly attached!
Just my experience.

Braided or woven conductors have several times the RF resistance of
smooth surface conductors the same diameter.

Braiding should be used only if the connection needs to be flexed, or
on short leads.

Weight can be controlled with a triangular-wave baud generator feeding a comparator, into the usual TO-style circuitry. That scheme will expand and contract the elapsed time between leading and trailing edges symmetrically, without changing rate. The cktry has its operational problems.

Does anyone know how Curtis chips do weight control?

I gave up on this one years ago and went that way, after trying a digital scheme involving a high-speed clock, division down, OR-ing, hopeless complexity, sigh ...

>RFI. What do you mean about going after this AM BCB station?
>I need some background here, please.

Hi Andrew..

I was wondering if it was the same station, I guess it is not.

I thought their problem came back.

The only stuff I hear now is the crap on 1830 from two stations in
Chatanooga that are mixing. The FCC has tracked that down to a problem
at one of the stations in Chatanooga Tn. When that is gone, I might
hear other stuff under it.

My point is mainly that sometimes BC stations are at fault, much of
the time the receiver is at fault and the stations are OK. You have to
know how to sort the problem out.

The rights are simple, the staions have a guidline for harmonic and
spurious suppression...but are still not allowed to cause harmful
interference. You just need to be sure to know how to tell who's fault
it really is before taking action.

Pete -

I also have a Titan and IC 746 . . .

Your GAP Titan does not need to be grounded and you can forget about radials. In fact, there is no way to ground it since it is a vertical split dipole.

For lightning protection, you can ground the mounting mast and/or use a lightning arrestor. GAP does not recommend long ground wires in any event as they start to act like an antenna themselves. They detune the GAP and, in addition, create all kinds of RFI. GAP told me to tape a foot or so of the feedline to your ground rod right at the point above where the feedline takes a right angle turn to go to your shack. Theory being the lightning will jump through the coax to the ground wire rather than turn 90 degrees and continue to the shack. I can't comment on how accurate that is but it can't hurt. It might help in a direct strike but it provides no "bleed off" of a building charge.

Check out www.polyphaser.com for a very good article about Ham Radio Station Protection. They say protection should be installed close to the antenna and away from the shack.

More GAP advice - - You must run the feedline down vertically from the antenna as far as you can before you run it horizontal or it will create RFI also. This is very important if you have 100 feet of feedline My GAP is on the roof and I run the line all the way to the ground some 30 feet before it turns horizontal. I had terribly RFI when I ran the feedline across the roof.

For grounding, I understand two 4 foot grounding rods 8 feet apart are better than one 8 foot rod. So, forget about going down 8 feet - you don't need to.

Your plan for a 6/2/70cm antenna makes no sense for the IC 746. It doesn't cover 70cm. And, it has a separate antenna jack for 2 mtr. In other words, you would have to hook the antenna up to 2 different output jacks to feed it on 6 and 2. Your GAP will load up on 6 mtrs (you won't use 6 very often anyway) so just get a 2 mtr. antenna and be done with it.

Running the feedlines close together should be no problem. If it is, your coax is radiating and that is not good.

I have the Mathcad 6.0 Professional version that I like very much. It is a couple of hundred dollars more than the basic version but has a lot of advanced features, several of which I have used. I have found that the cost of the more advanced version is justified because the extra power is there when I need it. It also does matrix operations quite well.

I also prefer it to spread sheets by a wide margin.

The Mathcad 2000 version has some extra features that are not important for me, so I will not upgrade, but I would recommend it as an initial purchase.

Agreed but the discussion was Outbackers vs Hamsticks vs Hustlers.
The Outbacker is not base loaded even using the 75M tap the effective
coil is 1/3 of the way up the mast. The 75M Hamsticks seem to start
the loading at that point also.

The most help for any of these type of antennas seems to come from
proper base matching. I'm not talking about base loading but matching
the impedance to the source.

Hi T

A quad is directional, that it receives better in the direction you point it.

If you want to work 2m repeaters or other on voice simplex you need to
aim the antenna in the direction of the other station. Most important,
is the polarization of the antenna, Vertical for the above and
Horizontal for ssb.

For Vertical polarization, you mount the antenna so the feed line is
at the right or left corner.

Horizontal you feed it at the top corner or lower corner.

Here a a nice site to help you, it has graphics of quad beam.
http://www.softcom.net/users/kd6dks/quad.html

Any more ? just post them and you will be on the air asap !

CCR's notification varies from state to state. In Maryland they have to provide you with a copy of the active CCRs in advance for new homes and on demand on all homes. In Illinois they don't have to provide them at all or even tell you they exists. However, you must sign a document that the home is part of a PUD and there are CCRs. When in doubt, place a request for ALL CCR's in advance and in writing, even those that are not active. If none are provided, if you make an offer, place in the offer that no CCRs are to be placed on the property and the seller will reimburse any and all moneys at anytime if any CCR's are on the property. If they do exsist, see if they are still active or legal. You should have seen the look and seen how fast two lawyers can move when I canceled the closing in the middle of the closing after they handed me my CCRs acknowledgement form and told them I was not buying the property for violation of this term in the selling agreement. I did settle, the restrictions were not a problem, sq. footage of house, fence, wells. BTW, there are many old expired CCRs. My mother cannot erect a fence beyond the front face of her home upto 1971. After 1971, she can put on up anywhere she wants but never has. There CCRs about selling to minorities which are mute now. I have a restriction on the use of barb wire and the size of my outhouse, like I really going to erect an outhouse.

If you are looking for a existing house look at homes built before 1965 or find a very knowledgeable Real Estate agent and let her know about will be placing this in all offers. If building, find a lot in non-planned development or older neighborhoods.

Best of luck

> have gleaned from Roy and Tom's comments.

I don't see how the current distribution could be optimum for maximum
broadside gain when the upper element is 5/8 wl in length. If maximum
broadside gain is the objective, the upper radiator should be very close
to half wave resonance. The idea is to minimize the current required to
feed the upper element by exploiting the so called 'antiresonance' at a
half wave. Roughly twice the feed current shows up as undesirable
common mode on the phase inverter which should be minimized.

> From Roy's earlier post, it seemed that he was saying that if you try to use
> a coil for the required phase shift you get reduced gain and and elevated
> lobe (not at horizon). As I understood it, there was still gain over a
> single 5/8 wave, but not at what appears to be a "useful" elevation.

Just because it looks like a coil doesn't mean it's a coil. The device
may electrically behave similar to a coiled up transmission line, or
self resonant tank either of which could be capable of generating the
necessary voltage and current relations if there was sufficiently low
common mode impedance to ground. Of those antennas I have examined, I
seriously doubt the common mode impedance is low enough to enable
maximum broadside gain but I can't say for sure without a careful
analysis.

> with a separate 70cm 5/8 wave and forget about the dual band "alleged"
> collinears that seem to be the rule of thumb these days.

There's a bit more going on... A mobile antenna in the typical urban
clutter environment can encounter very high levels of multipath
interference. Signal strengths tend to increase six dB for every
doubling in height and the antennas you describe do manage to increase
the effective height of the radiator in spite of acheiving less than

optimum broadside gain. A dB or two of lost gain may well be
compensated by the increased effective height.

My personal experience is that a 1/4 wl 'spike' on 450 MHz performs
every bit as well as one of the 'top quality' 1/2 wl over 1/2 wl mobile
antennas. YMMV of course.

> Do I have this right, or have I completely jumbled this up in sifting
> through all these interesting posts about the "collinear conundrum" ?

You got it right but be aware the thread has only touched on the basic
operating principals of vertical collinear antennas. The devil is in the
details, especially when considering the multipath mobile environment.

I'm currently sealing connectors with a Teflon foam (sold by AES - forgot the brand name) that is supposedly used in the cable TV industry. You fill up the PL-259 shell with the stuff from a squeeze tube, and then screw the connector together. It fills all the voids and even seals the thread. Haven't taken any of the joints apart yet, so don't know how it holds up over time.

Disruptive technologies usually have profound critics--such as yourself--who
make extra special efforts to attack:

1) without any support from fact;
2) targetted to discredit the individual for things actually not said,
implied, or inferred;
3) diverting the argument to base issues which have nothing to do with the
matter at hand.

Rest assured, in coming months, there will be yet more fractal antenna designs
for use for experimentation by hams. I am proud of the 'gung ho' attitude of
the amateur radio fraternity, and extremely plased to have presented a design
which has no peer in the small size I was asked to consider.

With best wishes,

Nathan Cohen, Ph.D.

Try a simple untuned vertical, the tallest whip you can get.
Mount it high, eg, on the roof of the building. Connect an
RF choke between bottom end and ground. Connect signal
across choke to the gate of an FET. The FET is a source
follower. Take the output from the FET source to your
equipment via a 75-ohm coaxial line.

You can feed the DC supply (9V, 5mA) for the FET source
follower over the inner conductor of the coax.

Oh yeah, I guess it would act like a large inductor with all the coils it has. I never really thought about that, but it make sense.
I don't know off hand without looking at it how many coils it has (I'm sending this message from work...shame on me!), the antenna is hung like a dipole about 13 feet across with the coils about 1/2 inch apart. It is fed with a 20 foot coax (50 ohm) going into one of the bedrooms. I'm not sure what kind of house wiring is behind the wall, but I'm sure there is something. I do have a patio with a 6 foot tall wood fence around it that I should try hanging it on and see what happens. I haven't tried that yet.

Jim

I've never thoght this could be better than a plain wire. If you need a good RF ground up in the air, put down a metal sheet (foil is OK) big enough to have fairly good capacitance to free space. Then you can use that as the local RF ground at frequencies where the capacitance is a low impedance. This does not replace the power safety ground and static drain, which can be a direct run of the appropriate sized wire to a good ground per your building codes.

Cortland

843. Folded Unipole

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-22 00:00:00 UTC
From: richardharrison@webtv.net
Message-ID: <13841-39A2CE25-32@storefull-118.iap.bryant.webtv.net>
Source record: 181973

In this newsgroup Roy Lewallen recently faulted Bill Orr for a claim that the folded unipole could be less lossy than a straight vertical antenna, after I said you could probably rely on Bill Orr.

After 40 years, I again have a copy of Laport`s "Radio Antenna Engineering", and it`s good.

Eb Laport says, the drivepoint resistance of a folded unipole with a pair of identical conductors will be 4 times that of a similar straight vertical antenna.

For instance, suppose we have a loss resistance of 13 ohms in series with our antenna system. With a straight vertical, the drivepoint resistance may be about 37 ohms, and with a power of 5000 watts (use milliwatts if this offends your amateur radio sensitivity), our current is 10 amps. Our loss is 1300 watts.

With a folded unipole whose drivepoint resistance is 148 ohms, our current is 5.57 amps into 161 ohms. Our loss is 404 watts in the same 13 ohms.

404 watts is less than 1300 watts, thus it is possible to reduce antenna system loss by using an antenna whose drivepoint resistance is a larger fraction of the total system

>accomplished by the loss due to capacitive matching to the body of the
>small imported rental car.

You'll note that I always say that the worst antenna I know of for mobile HF work on 75 or 40 meters is a base loaded whip.

I've actually played with an Outbacker on a reasonable mount on a mast, which placed it above the roof of the vehicle, the results were still less than Hustler resonators or even a Lakeview hamstick. I still think that there are uses for the Outbacker as I oiginally said, but for hams with the same vehicle everyday, they just aren't a cost efficient or good choice. They're sturdy, and well engineered, and allow multiple band usage with only a small amount of attention to detail (moving the wander lead & adjusting the "stinger") but at best, they're spiral whips. Something I didn't try was using one as the stinger for a center loaded coil, but of course that probably defeats the purpose.

I also note that I've seen one mounted on a motorcycle, and it actually made sense to use one for the motorcycle, but specialized usages don't mean that it's normally a good buy.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39A2E44D.72ED7E18@eznec.com>
Source record: 181976

Sigh.

Let's take your number of 13 ohms "in series with our antenna system", i.e., ground system loss. Your monopole puts, as you say, 10 amps into the ground system for a total of 1300 watts.

Now, take a close look at how your folded monopole is connected to ground. One side of the source is connected to ground. What you and many others forget about is that one conductor of the monopole is also connected to ground. So the bottom of the source is connected to the bottom of the other monopole conductor, and the combination is connected to the Earth through 13 ohms. An easy way of looking at what happens is to observe that the current from the bottom of the source is now half of what it was with the unfolded monopole. (I'm neglecting, for simplicity, the modification in feedpoint resistance caused by the loss, but I'll include that in the more detailed analysis.) The current into the ground system from the other monopole conductor is equal to the current from the source, and is in phase with it, so the net current into the ground system is just what it was before. Consequently, the loss is the same as before. This is what I explained to Orr many years ago, and what has been posted here a number of times (most notably after the claim that the Uni-Hat was more efficient because of folding -- a claim which I don't believe is any longer being made).

A more detailed analysis goes something like this. The current from the bottom of the source and the current from the second monopole conductor are equal and in phase. So we can split the ground resistance of 13 ohms into two parallel 26 ohm resistors. That is, the bottom of the source can be considered to be connected to the Earth through a 26 ohm resistor, and the second monopole conductor through its own 26 ohm resistor. These resistors can be separated so they don't share current. (Because equal currents flow through the resistors, the voltages at their tops is equal, allowing us to separate them.) Now, the source sees 148 ohms + its ground resistor of 26 ohms + 26 ohms of resistance from the second monopole conductor resistor. (There's a 1:1 transformation of this resistance in referring it from the end of the second monopole conductor to the feedpoint. You can verify this with EZNEC, or analytically if you'd prefer.) So the source sees a total of 200 ohms. At 5000 watts, the current is exactly 5 amps. 5 amps flows through the 26 ohm resistor at the base of the source, for a loss of 650 watts in that resistor. 5 amps flows through the 26 ohm resistor at the base of the second monopole conductor, for a loss of 650 watts in that resistor. The total loss is 1300 watts, precisely at it was before.

Feel free to use some other way of analyzing the loss with the folded monopole. Just don't ignore the current going into the ground from the second monopole conductor.

Roy Lewallen, W7EL

purchase.

The only problem with not upgrading is the worksheets are not fully backwards compatible with earlier versions, even if they are saved as a prior version. The only time somebody will find out is when they load the worksheet and find an equation area inserted as a bit-map. The only way to avoid the problem is to keep a copy of the manual around to reference (for the version you want to save the worksheet in) so you don't use functions that don't exist in it. I don't know why Mathsoft can't highlight the functions that don't exist in a selected prior version so you don't have to play the save and try it out game. Otherwise It is a great program which I have used at work, home, and for some class projects I had to do a few years ago.

>same amound of time as the dots.
>As a consequence the ratio between them is not constant.

You're right. I checked the algorythm of a keyer I helped do and
that's what we did in the software and it sounds fine. I remember we
did a couple of attempts that "sounded wrong" when weight was
adjusted.

We shortened the dots and dashes by the same amount, and quantify the
weight only by dots. But that isn't based on a ratio change between
dot an dash length. It's a duty cycle change. I think the reason it
sounds OK even with an unintentional ratio change is the range of
weight change is limited, so the ratio never changes that much.

I have a second keyer IC (I almost said a taboo word) I have where we
changed the dots and dashes by the same percentage, keeping the ratio
the same, and adjusted the space between the dots and dashes to keep
the speed the same. It sounds OK also. The CW gets lighter and
heavier, and not "swinging". But again the range of weight control is
limited.

The only thing that sounds whacky, and doesn't adjust the duty cycle
without making the code sound like it is sent with an old side swiper
by a drunken telegraph operator, is changing the ratio. No one in
there right mind would want a ratio change, like my 706 Icom has.

So tell me Jan, which way of the two decent sounding ones do you think
sounds correct? Anyone else?

Is this documented anywhere? Or is it like S units?

Where did "heated up" come from? I don't get it.

The last thing you want to do is have shunt capacitance in an area
where the voltage is high. Using a tuner to feed a whip does just
that.

>results.

Hunh? You miss the point I think. For 40 meters and below:

If you placed an antenna with a fair amount of reactance in the
loading inductor in the middle of sixty 1/4 wl radials and compared
that system to an inductor with twice the Q, doubling Q would almost
cut losses in half. The inductor ESR dominates the system.

If you placed the antenna on a vehicle and doubled inductor Q in the
same antenna, the change would be barely or certainly much less
noticed.

If you placed an antenna on the radials and moved from near-base
loading to near-top loading, the change would be small and more
related to how the reactance required changed.

If you placed the same antenna on a vehicle and did the same change,
the change to top loading would be much more noticable.

As I said below:
>>The smaller the vehicle, the more important current distribution in
>>the antenna becomes.
>>
>>Hams that think large diameter coils offer optimum performance are
>>missing the boat. Even a #14 wire coil can have Q of around 300 in a

>the loading at that point also.

Comparing three marginally designed systems doesn't tell us anything
about how good any of them are.

>The most help for any of these type of antennas seems to come from
>proper base matching. I'm not talking about base loading but matching
>the impedance to the source.

Actuallt the biggest help is increasing the stinger or capacitance at
the top on the antennas, and using less inductance. Bandwidth gets
wider and efficiency higher.

A Hustler, with enough capacitance above the coil so the 20 meter
resonantor works on 40, is a real good 40 meter antenna.

The Hustlers problem is too much shunt C across the coil, and that
murders Q. The Hamstick and Outbackers problem is the small diameter
and small wire in the coil. All of these antennas have dielectric
materials surrounding the coil, which also reduces Q.

What I have done is roll up the carpet, and lay down aluminum foil
over a criss cross of brass or copper foil that forms the leads. I
guess you could use wire also. Then lay the carpet back down.

Does the trick for a RF ground, makes the whole room "cold" for RF.

>Eb Laport says, the drivepoint resistance of a folded unipole with a >pair of identical conductors will be 4 times that of a similar straight >vertical antenna.

Drivepoint resistance is not directly related to efficiency or ground loss. I can make drivepoint resistance anything I like, and not change efficiency, when all I do is tap the source across different parts of the system with changing the common mode current toatals in the system.

>For instance, suppose we have a loss resistance of 13 ohms in series >with our antenna system. With a straight vertical, the drivepoint >resistance may be about 37 ohms, and with a power of 5000 watts (use >milliwatts if this offends your amateur radio sensitivity), our current >is 10 amps. Our loss is 1300 watts.

OK.

>With a folded unipole whose drivepoint resistance is 148 ohms, our >current is 5.57 amps into 161 ohms. Our loss is 404 watts in the same 13 >ohms.

Nope, you totally missed the boat. You simply split the current between two conductors. Since applied power is the same, and current the feedline sees is halved, the voltage must double. You have twice the voltage and half the current, so impedance seen by the feedline quadruples.

The other half of the system, the side connected to the ground system directly, has 5 amps in it. The side that passes through the feedline has 5 amps in it. They both tie to the ground system, so current in the ground system is 5 plus 5 or 10 amperes.

This assumes each conductor is equal size and shares equal current. If one is thicker than the other, it hogs more current so the rations can be different (and impedance transformation some value other than 4:1) but the sum of currents entering the ground will always equal the original current in the marconi feed system.

If I disseminate a Mathcad worksheet, like in an article, I make it as generic and simple as possible so that the most basic versions can be used. If there is a version conflict the reader can easily type in the material using his own version.

Tom,

I think that larger dia. wire and larger coils DO have higher Q---up to a point. Small dia coils with smaller wire and closely spaced turns are often lossy. When you get over about 4" coil dia., you have passed the point where return begins to diminish. Some of those "monster" coils DO have high Q, BUT that efficiency works against itself in that they become so sensitive to their surroundings that one would be just as well off with the smaller coils you mentioned. These coils, at least the bug catcher types, because of their fixed tuned characteristics, cannot respond to the changes in their environments (such as a screwdriver can), and can be put out of resonance merely by moving the vehicle a few feet from where the tap was installed. I see some of these HUGE bugcatchers at hamfests and wonder how the operators can get any results at all when under way.

My screwdriver is like Henry Allen's Texas Twister--3" diameter and about 9 feet long fully extended (13' from ground). Whip is 60" long. I wish we could have some nearby tests so I could see how mine works against some other types. I mean, when you make something, nice to see how one compares.

The phrase keep away from conductive surfaces without stating how far
has had many think that it requires a great distance..

It is recommended that you maintain a distance of about 2ï¿½ to 3 times
the center to center of the conductors of the ladder line..

For example, the popular (so called) 450 window line has a 0.8"
spacing. Therefore keeping it 2ï¿½ -3" or so away from conductive
surfaces is enough.

Hope this helps

A local fellow tuned me in on how to waterproof connectors:

Wrap with rubber tape. Use some tension and overlap.
Wrap that mess with Scotch (3M) electrical tape.

I recently took down an antenna that was up 3 years and
the connectors were still shiny.

Reg wrote: "Folding does nothing more than multiply the unfolded feedpoint resistance by four. The feedpoint resistance is radiation + loss resistance."

Nice to see them agree!

From Arnold Bailey, the radiation is identical from the 1/4-wave vertical or from the folded unipole. So, lossless antennas have the equivalent of equal total currents in their elements.

Roy wrote:
"So the bottom of the source is connected to the bottom of the other monopole conductor, and the combination is connected to the Earth through 13 ohms. An easy way of looking at what happens is to observe that the current is now half of what it was with the unfolded unipole."

My schematic has 13 ohms in series with the transmitter output. I did not consider any significant loss in the antenna elements themselves.

In the case of a 1/4-wave straight vertical, I had a 50-ohm total load.

In the case of the folded unipole, I had a total load of 161 ohms.

Each load has the same 13-ohm loss resistance in the circuit. The loss is a part of the total resistance in each case.

(I squared)x(Rloss) for the 1/4-wave straight vertical is 10 amps squared times 13 ohms = 1300 watts.

(I squared)x(Rloss) for the folded dipole is 5.57 amps squared times 13 ohms = 404 watts.

The advantage of higher impedance is lower power loss for the same power transmission. It`s why audio isn`t distributed at 8 ohms, and it is why electrical power isn`t transmitted at 110 volts over long distances. The same loss resistance would rob circuits of a higher percentage of the power at a lower transmission voltage to current ratio.

Best regards, Richard Harrison, KB5WZI

I believe that the ARRL policy was, and may be still, to rewrite roughly 20 percent of the book every year. If this is still the practice, every 5 years or so would be a reasonable interval. Of course, during that time some sections would be rewritten more than once and some not at all. At times, they've done a complete rewrite and/or reorganization of the whole volume at once. This happened with both the Handbook and Antenna Book some years ago. As I recall, the Handbook was done some time between about 5 and 10 years ago, with various sections and chapters being written by different authors. The Antenna Book was completely redone by Jerry Hall at around the 14th or 15th Edition. (The thickness about doubled, so it's easy to tell old ones from new.) I heartily recommend getting one of the later Antenna Books if you've got a pre-rewrite one.

Particularly in the case of the Handbook, the content changes as the technology changes, so people often find it useful to have several editions, if they work with technologies of different eras or deal with older equipment. The projects also change from year to year, so this is another reason some might choose to have more than one.

Yes. One half is in each wire.

The dominant source of loss in a ground-mounted monopole system is ground loss, which does not appear in series with the transmitter, but at the connection(s) betweeen the antenna and ground. This is the model I used. If ground loss isn't a factor, a monopole, either folded or unfolded, would be so close to 100% efficient (unless extremely short) as to make it not worthwhile to consider loss at all. I can't think of any significant cause of loss in a real monopole which can be reasonably modeled as being in series with the source. You could, of course, refer the ground loss to the feedpoint. If you do, you find that it's transformed by the same factor as the antenna impedance. That's basically what I did in my detailed analysis -- you'll recall I ended up with 5 amps -- the source current -- going through two 26 ohm resistors. You can refer the 13 ohms of ground loss to the feedpoint as a 4 X 13 = 52 ohm resistor, have the source current of 5 amps flow through it, and get the same result. You get the same result with any valid analysis technique.

Your analysis is correct if you've put a 13 ohm resistor in series with your source. But not if the 13 ohms is ground system loss. Your analysis isn't for an antenna mounted on a ground system having 13 ohms of resistance. It's for an antenna with a 13 ohm resistor added in series at the feedpoint. For your antenna model, your analysis is correct. But I doubt many people are interested in the efficiency of that system.

How do you get 13 ohms of loss in series with the source in a real antenna without purposefully adding a resistor?

The "dielectric grease" I've seen is a silicone grease. I know plumbers use silicone grease for lubricating seals -- have you or anyone tried getting it at a plumbing shop?

It's also used for lubricating O-rings, so some industry which would have a need to do this should also have a source.

I'm still using a large tube of the stuff I got somewhere surplus about 30 years ago. A little goes a long way! But I haven't used it to fill connectors.

Big THX to all. Both I and 1310 WDCT are located in
Fairfax City, VA. 22030. I've taken down the antenna (See,
"Project Skywire, No More", new post). Still, there's a new wire
up and so I'd like to finish this thread properly. First of all, I'm a
newbie and don't know what my rights are re: other peoples'
RFI. What do you mean about going after this AM BCB station?
I need some background here, please.

Tom, email or post here if I can give you any helpful info
on this station.

Thanks,

Andrew

872. Project Skywire: No More!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-22 01:55:01 UTC
From: cathexis@erols.com
Message-ID: <39a1d6de.251428078@news.erols.com>
Source record: 181936

Greetings,

That's right; 24 hours after I put it up I took it down.
Reason? The east leg of wire was barely over the roof and
worse, 10ft. from my power line. Though trees were good,
no insulators or tie-offs were used and I felt this posed an
un-acceptable risk. Had that leg of the circuit snapped the
only place it could have gone is sliding off the roof to drape
on the power lines. I refused to take that chance.

But,.....Now there's a new wire! Haven't even really
checked it out yet. Will have to see about previously mentioned
BCB RFI. There are pluses and minuses to this wire. First it's
no loop, just a random wire. Only 130ft. approx, not the 200ft.
of earlier one. One nice advantage: Height! Whereas the pre-
vious wire probably averaged 30-40ft. This new one came from
some *really* lucky slingshots that sent my fishing weight into
genuine tree tops. Avg. height now: Never less than 50ft,
with a third of the length approaching 80ft plus.. Yumm!
That's just about all the up I've got <grin>.

I would like to ask the ng for some advice. I still have
well over 60+ feet of wire (more if I splice) and two huge trees
well placed at same heights but,..... This means turning a "L"
shaped random wire into either a "J" or something very close
to a Right Triangle-- depending on how far I bring the wire
back to close the circuit. Still, I've read and heard talk of how
anything that gets to be a "folded dipole" will actually LOSE
gain. If I put up more wire I would get perhaps another 70-
80 ft. in length and maintain same good altitudes. Thoughts?
Reasons for your thoughts?

Again my thanks,

Andrew

The issue has to do with the fact that the loop is a shorted loop at DC potentials and polarization comes into play also. Much man-made noise is vertically polarized and that is why the vertical has more noise in many instances (mine included).

My tests were conducted with stations at virtually every direction on the compass so it is not a matter of directionality as far as I can interpret.

There are numerous references regarding the characteristics of the loop based upon computer modeling, antenna range tests, and empirical data collected at various ham locations. For the interested parties, just send me an email and I will compile a listing of the authors and articles. If it would be helpful, I can copy the articles and send them out.

The antenna patterns I've seen for loops differ somewhat from a dipole and do experience some degree of gain over a dipole depending on the elevation angles, height above ground in terms of wavelength, ground conductivity, etc. There are too many variations to expound on in narrative form so I'd be happy to copy the plots from the models too.

Note that I merely wanted to convey what I have read and what my tests have indicated. Others might have different experiences due to local conditions. In any case, antenna experimenting can be fun.

Yes. I love those GPS.
But for now. The accepted method of timing scientifically meaningful
events. Is to stick a videocam on your telescope, and videotape the
event while feeding the UTC radio broadcast to the audio track. Some
amateurs are working on an interface circuit that will insert the GPS
time signal on the video frames. But until they succeed (and then
again). Hundreds of astronomers around the world will continue to use
short-wave radios to record their measurements.

.
The Outbacker tested was on a mag mount with no attention paid to base
matching and/or grounding. Reasonable match to the transceiver was
accomplished by the loss due to capacitive matching to the body of the
small imported rental car.

You can gain a bit by grounding an Outbacker and matching the load.
It's pretty much the same as a Hustler or Hamstick. As you can see
from the results you just don't get there on 75 until you get a center
mounted coil of some reasonable diameter.

The most interesting thing of the lot was the stainless steel coil
bugcatcher. It was very much a copy of the 480 coil that Henry
Allen makes but in stainless. Guess that makes a case for
ohmic losses and efficiency.

> spaces).
>
Tom, I am a little confused.

33% weight makes the dots 2/3 of the original length.
If dashes are/stay 3 times the dots, then
dash length = 3 * (dot length * 2/3) = 2 * dot length?

A weight of 67% makes a dot twice as long as the off period.
So the dot becomes 4/3 times its original length.
dash length = 3 * (dot length * 4/3) = 4 times dot length?

In the last example dashes fill up a full space.
The spaces between dots and between dashes are not the same.

As far as I understand the dashes are shortened or extended the
same amound of time as the dots.
As a consequence the ratio between them is not constant.

As you said Tom:
> In early keyers, that was accomplished by changing the threshold
> point of a triangle wave triggering system.

You are all making a song and dance about the (John Cleese) bleeding obvious. Some of you might be trying to make a living out of it. Good luck to you !

The radiating efficiency of a 1/4-wave folded monopole is exactly the same as a 1/4-wave simple monopole, regardless of the base-ground connection-loss resistance. Folding does nothing more than multiply the unfolded feedpoint resistance by four. The feedpoint resistance is Radiation + Loss resistance.

Instead of folding it is quite feasible to use 3 conductors in parallel and feed only one. The feedpoint resistance is then 9 times the simple 1/4-wave vertical or roughly 330 ohms.

But the radiating efficiency of the system remains unchanged.

There's no such thing as a free lunch.

Roy Lewallen wrote:
"I only said that the current into one terminal has to equal the current out of the other,"

No argument with that as a steady-state statement. There is no long-term storage in an inductor.

I was challenging the statement "The currents at the terminals of an inductor are in phase."

An "ideal inductor" has zero resistance (don`t know about zero size) and not only opposes current as described by Lenz`s law, but delays current flow.

In a purely resistive circuit, the current is in phase with the voltage. If purely inductive or capacitive, the current in a circuit lags or leads the voltage by an angle of 90 degrees. If inductance is in series with resistance, the current lags the voltage by an angle whose tangent is X over R.

What is the function relating current in and out of the inductance? The current in the circuit is the voltage divided by R + JX.

The function of current out versus current into a perfect inductance is that no delay happens in the resistance (even if there were some) it is all in the inductance. There is a delay of 90 degrees in a purely inductive circuit. There is zero delay beyond wave propagation time in a in a purely resistive circuit with zero inductance.

Delay is obvious when d-c is applied to an inductance. Put one volt across a one henry tnductor with one ohm total series resistance, and in one second the current will have risen exponentially to 63% of its final value of one amp. The time constant is proportional to L over R. (If the same one-ohm circuit had a coil of two henries inductance, it would take 2 seconds to get an increas up to 0.63 amp through it) T, the time required to reach 63% of the resistance limited current through the circuit, is a function of L/R, as said above.

I remember when certain chokes were called "retard coils".

I'm sure there are a lot of good engineers, but there are also more
"engineers" now than there used to be...especially with small
stations.

I think it's more an attitude problem caused by years of no
inspections and no enforcement than anything else.

That's a rip-off for skilled professionals as well as the public.

Dennis Furguson wrote:
"At the risk of stating the obvious, the fact that the voltage across and current through an inductor are out of phase says nothing about the relative phase of the currents at each terminal."

Well, we were considering a series circuit with all currents going through all components.

There are actually at least two currents in the circuit. One current is imposed on the inductance. The other is self induced in reaction to the imposed current. These are in phase opposition. The net current is effective in the circuit.

There is nominally a 180-degree difference between the coil terminals. If the voltages and currents were the same at both terminals, they could be shorted with no consequence.

Oh yes, the cables all come down to ground level (but I don't have them
grounded at that point, that is my next step; to run a ground wire from
the coax shielded braid to my ground rod near by)... and yes, I have the
tower grounded for RF and lightning both.

Maybe the problem is one of semantics. By "equal", I meant, well, equal.
That is, equal in phase and in magnitude. You must not agree with this,
or you wouldn't have written the sentence above.

> An "ideal inductor" has zero resistance (don`t know about zero size) and

Can you please give us the equation which describes the current delay
from one terminal of an inductor to the other? I2 = F(I1)?

> In a purely resistive circuit, the current is in phase with the voltage.
> If purely inductive or capacitive, the current in a circuit lags or

How does voltage keep getting into this?

> What is the function relating current in and out of the inductance? The
> current in the circuit is the voltage divided by R + JX.

No, this isn't what I asked for. You've given an equation which relates
the voltage to the current. I'm asking for the equation which relates
the current at one terminal of the inductor to the current at the other
terminal of the inductor.

> The function of current out versus current into a perfect inductance is
> that no delay happens in the resistance (even if there were some) it is

So you are saying that the current at one terminal of an inductor is in
quadrature with the current at the other terminal, regardless of the

value of the inductance or the frequency? That is, your equation is I2 = -jI1? This is a perfect Hilbert Transformer. I've been looking for one for decades. It's just what's needed for feeding phased arrays.

Unfortunately, it also doesn't exist. Build yourself a couple of simple current probes with ferrite cores, as I've done. Put one on each end of an inductor and watch the currents with a dual-trace oscilloscope. What do you see?

I'm failing to communicate. I know that current lags voltage in an inductor. Everyone knows current lags voltage in an inductor. But what does this have to do with the relationship between the currents at the inductor terminals?

> I remember when certain chokes were called "retard coils".
>
> Best regards, Richard Harrison, KB5WZI

Is this just me? Is there something about the way I'm asking the question that's not clear? Did I ask something about voltage without realizing it?

Greetings to the group.

Sorry to stray from the antenna format, but from what I read many on this group are into contesting. I am in the market for logging software. I know that there must be several available, but as of yet I am unable to locate any. The program that I am looking for seems to me to be rather simple. I want it to show "dupes", time, date, frequency, call, and the other usual basic information. I am not particularly interested in software that will control my radio, or packet software.

Thanks to anyone that could help me..

I've built and used a variety of vee-beams. They are nice antennas, the
only disadvantages in my opinion are that they are large, and the main
radiation lobe is fairly narrow.

For multi-band use, I feed them with open-wire line going into a
Johnson Matchbox antenna tuner.

> through all components.

By definition, a series circuit is a circuit where the exact same instantaneous current flows through all of the components. The instantaneous current entering any component is exactly equal and opposite the the current leaving the same component. Therefore, the component does not accumulate charge. The current leaving the previous component is exactly equal and opposite to the current entering the next and so on.

If the instantaneous currents are equal, than the phasor representation of _any_ current in the circuit will be of the same phase. This relationship is true regardless of the phase relationships between the current and various voltage drops around the series loop.

There will always be a current maximum 1/4 wl from an unterminated end.
Therefore, an end fed 5/8 wl radiator is fed 3/8 wl from the current
maximum.

> To get 180
> degree delay between adjacent current maxima in end fed, collinear 5/8 wave
> radiators, you need another 3/8 wave delay. I suspect that's what the coils
> are set up to provide.

The problem is that a three terminal device is required to create the
necessary delay. There is no way for the current entering one terminal
of two terminal device to be any different from the current leaving the
other terminal unless the device is capable of storing charge. By
definition, a two terminal device, such as an idealized inductor or
coil, is a two terminal device and does not provide the third terminal
required of a phase shifter. Real world components present capacitance
to space and are therefore capable of limited common mode current
(charge accumulation) to ground. Something like a 1/4 wl stub, tuned
counterpoise, or connection to ground are necessary to provide a low
impedance 'ground' for the common mode current.

Roy Lewallen wrote:
"The currents at the terminals of an inductor are in phase."

The problem may be that we are not assuming the same circuit. Let`s say we have a generator connected to a load through an inductor. The inductor causes a lagging current, but that is not relevant.

The load, being a perfect resistance does nothing to significantly delay the current. Thus, the generator output is applied to the inductor via the load, a resistance, but there is a voltage difference across the inductor because it isn`t a short-circuit and because the terminals of the generator are 180 degrees out of phase and this gets passed on to the terminals of the inductor.

The net current at a single frequency has a single direction in a circuit. So, maybe, "The currents at the terminals of an inductor are in phase", is (1) nonsense, or (2) completely wrong. There are two currents at the terminals of an inductor (1) that imposed by the generator and (2) that resulting from self induction, and these two currents are in opposition, or out of phase.

Best regards, Richard Harrison, KB5WZI

By flat top section, I mean NOT the tapered one.
I was wondering what others have done to keep the coax out of the way when the rotor is turning. In the past, I just made a loop around the rotor. But, that was with mast mounted rotors. Now I have the tower, and it is more of an obstacle for the coax to rotate around.
Thanks for the read....
PS...If you have had lots of 25G experiance, I would also be interested in chatting. I just put mine up, but still slapping up antennas.
Regards....Dave

Dave- I don't have a lot of experience, but I do have the flat-top 25g.
My set-up, reading from the rotor plate up, is: rotor, top section of
tower (between braces) top plate (flat top) bearing, and tri-bander.
The mast mounts in the rotor, through the bearing, and up to the
antenna. The Coax comes up through the tower (opinions differ on this),
out through the top section of braces (outside the top plate) and up to
the natenna. THe coax is taped to the mast below the antenna to take the
strain. There is enough slack (loop) in the coax for the mast-antenna
assembly to move full circle.

Works for me- Bill- W4BSG

More formally, the algebraic sum of the currents into the two terminals
of any two terminal device is zero.

Are you saying the two currents do not sum to zero?

> There are two currents
> at the terminals of an inductor (1) that imposed by the generator and
> (2) that resulting from self induction, and these two currents are in
> opposition, or out of phase.

I am not sure what you are saying. The voltage drop (Volts) across a
pure inductance is equal to -L * di/dt where L is the inductance
(Henrys) and di/dt is the time rate of change of the current
(amps/second) flowing through the inductance. There is only one current
through the inductance and the voltage drop is exactly proportional to
the time rate of change of current.

It doesn't matter if you consider the voltage across the inductor to be
caused by self induction, or simply the applied voltage. Either way,
the voltage equals -L * di/dt and the currents entering the terminals
sum to zero.

An inductor does not accumulate charge.

An inductor does store energy. The stored energy is proportional to the
current squared and independent of the terminal voltage. The rate of

change of stored energy is equal to the terminal voltage times the current.

Well shoot, Tom, most of the "rusty bolts' end up on guys anyway. Places where they don't have direct pressure. And they don't have to be bolts. Or even visibly rusty. Just nonlinear.
IIRC the folks on the Prudential Building in Boston are STILL arguing who pays to fix the IM
there -- the building owner says he built according to accepted practices, and the radio folks will have to pay extra if they want all the rooftop metal bonded.

A man could do some EVIL with a little wire and some diodes!

Source record: 181797

Ok, one last time. This time we'll talk about exactly the same circuit.

Let's use your circuit of a source, inductor, and resistor all in series. (Hook the inductor to the positive terminal of the source, the resistor to the negative terminal, and then connect the resistor and inductor together. Define the negative source terminal as zero volts.) Let the source voltage be Vs, the inductance L, the resistance R, and the radian frequency w (for omega). Then the impedance seen by the source = R + jwL. The current EVERYWHERE IN THE CIRCUIT is Vs/(R + jwL). The voltage at the inductor-resistor junction is Vs*R/(R + jwL). The voltage across the inductor = the voltage at the source-inductor junction (the source terminal) minus the voltage at the inductor-resistor junction = Vs*(1 - R/(R + jwL)) = Vs*(jwL/(R + jwL)). The voltage across the inductor can also be calculated as the current through the inductor times its impedance = Vs/(R + jwL) * jwL = Vs*(jwl/(R + jwL)), the same result, as it should be.

The voltage across the resistor is R times the current through it = the voltage at the resistor-inductor junction, shown above. The ratio of voltage across R and the current through it is simply R, the impedance of the resistor. It's purely real, as it should be.

The relationship between the inductor voltage and current (its impedance) is jwL. In phasor terms, the current lags the voltage by 90 degrees, as it should.

Let's try conservation of energy. The power supplied by the source = Vs * Re(I) = Vs * Re(Vs/(R + jwL)) = Vs * Re(Vs*(R - jwL)/(R^2 + (wl)^2)) = Vs^2 * R/(R^2 + (wl)^2). The power consumed by the resistor is |I|^2 * R = (Vs^2 / (R^2 + (wL)^2) * R = Vs^2 * R/(R^2 + (wl)^2). This equals the power delivered by the source, as it should.

So I've given the voltage at each node and the current at each point in the circuit, the impedance of the load, and the power being delivered by the source and consumed by the resistor, using elementary circuit analysis.

Please take a few minutes and do the same using your contention that the current isn't the same everywhere in the circuit. The result should be interesting.

I have no experience with the tuners that you mentioned Pete but I'm using the SGC SC-237 "SmartTuner" at QRP levels with a 50' wire and a relatively poor return (ground) and I have had good luck on all bands from 80m through 6m (quite directional on 6m). I realize that there are more efficient antennas but it "works good for me", what ever that means. I've used better antennas before but I still work a lot of DX on 40m through 20m with QRP so for restricted areas I believe it is a viable option.

Boy is it a simple, worry free setup!

You suppose correctly, though their may be a bit else going on in the feed system to achieve match.

When the dipoles are all on the same side of the support, the azimuth pattern is modestly directional. The spiral arrangement is an effort to make the antenna more omni. You also will see pairs of dipoles on opposite sides of the supports with alternate levels rotated 90ï¿½ around the support.

Source record: 181800

Hi Every one,
It about time I got myself onto 160 m mobile but
need to look at the antenna possibilities.

The preference would be to build my own and I wonder if anyone has note of
any web addresses that have good designs available?

Obviously efficacy of such a small antenna is suspect, so any comments of
the best (usable) design would be of interest.

Thanks, Malcolm...

916. Lakeview "Plate Mount" for Ham Sticks, Comments?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 00:00:00 UTC
From: jhulet@aol.com
Message-ID: <20000823033936.15434.00000880@ng-cl1.aol.com>
Source record: 181853

Hello,

I came across an interesting mount for HF mobile whips... This is Lakeview's "Plate Mount" for mobile whips with a 3/8" X 24 thread. I have a Jeep Cherokee with a metal back hatch. I am wondering if the hatch itself will be enough of a ground for the whip antenna with this Lakeview Plate Mount attached with bolts to the metal of the rear hatch. This sounds like a "cleaner" setup the my current three magnet mag-mount that I am using now. But I am not willing to run grounding strap all over the back of the Jeep in the process. I get great performance with the mag-mount setup and I am pleased for the most part. The plate mount looks nice and would stop the scratching up of the roof ot he Cherokee and would keep the coax out of the rear passenger door...(not a good thing I know).

Anyone using this sort of mount? The plate on a Jeep Cherokee is in the rear hatch above the rear bumper.... Not sure what this location will do to the SWR?

Thanks for any comments...

Jason S. Hulet

Tom, I think I prefer the first one. May be because I am familiar only
with this scheme. I use only small changes (+/-5%).

> Is this documented anywhere? Or is it like S units?
May be a good question for the alt.ham-radio.morse newsgroup HI.
Of course we can treat it like S-units. CW by hand-key is always
weighted more or less. Everyone uses its own definition of weight.

By the way:
Checked my TS870, abt. 6dB between S1 and S4, but 12dB between S7 ans
S9.
Also S9 and up to S9+60dB is accurate enough to talk abt dB's.
May be the 60dB is closer to 50dB, but I dont' care.
When I want to measure, I use a (calibrated) measuring-instrument.

To get the ladder line inside the house, I replaced one pane of glass
with plastic, then drilled holes as appropriate. Worked fine, and
when I sold the house later on, I just reinstalled the glass.

Placing the pair of insulated wires close together for a few
inches and bringing them indoors through one small hole in
the window pane or window frame has an insignificant effect
on line performance at HF.

Its equivalent of a couple of picofarads in shunt with the
line at that point. It is 'corrected' by an un-noticeable
readjustment of the tuner capacitor.

Ohh, that hollow cable.

I never use that, because water dribbles out of it after a period of
time. During the daytime, it get heated. At night, no matter how I
seal it, it sucks humid air in. The next day the heat pushes the air
out but not the water.

I imagine it would suck the flooding compond in also.

>Best regards, Richard Harrison, KB5WZI

The feedline isn't the problem. The antenna is.

In an audio system, the 600 ohm distribution impedance is stepped down
through trnsformers at each speaker.

Same with an antenna and the folded monopole.

In an audio system the speaker is just as efficient with a four ohm
coil as a 40 ohm coil, same with a folded monopole.

With a folded monopole you can use a higher impedance transmission
line, but your original argument was about ground loss...not feedline
loss.

Bill Orr ought to remove the error about folded monopoles from his
books and articles, and try to undo the damage he has caused.

930. Re: Ladder Line - with balun box

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 00:00:00 UTC
From: k4ia@aol.com
Message-ID: <20000823073225.28945.00000211@ng-fe1.aol.com>
Source record: 181867

I am curious about the W9INN "balun boxes." You run coax from the shack to the 4:1 balun box and then ladder line from the box to the antenna. Seems the best of both worlds if you have to run near metal.

But, does it really work or does the coax defeat the low loss advantage of the ladder line? I suspect we are working with the same loss per foot of coax formulas so a "short" piece of coax would really have little or no effect.

Any comments?

Message-ID: <R_Oo5.65831$dC1.91643@dfw-read.news.verio.net>
Source record: 181869

A friend and I are installing a VHF Marine radio in his 1989 5th wheel.
He's placed a Shakespeare 5206-C antenna on a 15' pole. The camper is
already wired for cable TV, which he would like to use for this application.
. I know some of the cable run is RG-59, but am not sure if all of it is.
The antenna came with RG-8 or RG-58 (the smaller diameter of the two). Can
we mix and match these cables? Will the RG-59
work OK for these marine frequencies? Generally speaking, is cable TV cable
appropriate?
For this application? What cables (types) are appropriate to use
in this application? If this is an inappropriate news group to ask theses
questions, please
suggest another. Thanks.

Ted,
I don't think that mixing the RG-58 and RG-59 will work out
too well. I'd suggest re-running the feed line with the recomended
type.

Bruce,
Any 'lost' radials should contribute to a better performance
of ~any~ antenna. They don't necessarily have to be connected
electrically (connected is better). Wire buried in the ground
doesn't last too long. But, rust is metalic, it still 'adds'
to your ground system.

The way I used to do it on ship was to wrap the connector with rubber tape, then wrap with vinyl electrical tape, then apply a coat of 3M Scotchkote(TM). When done right, I know that the connectors would be bright and clean after one year since this was the maintenance interval on the antennas on ship. I don't think that many hams have the seaborne enviroment that exist on a naval ship.

John & Deb,
I used a 1x6 board, drilled holes the correct distance apart,
ran the Ladder line through the holes, 'hot glued' the wire in the
holes, and forget the impedance 'lump' it makes. Make the board
fit the window opening. You can also use bulkhead connectors
through the board for coax.

A better approach for "untuned systems" would be to simply use two
shielded cables (like 75 ohm cables) in push-pull, or shielded
twinlead, for the connection. If you want to use a balun, a 1:1 choke
balun would be better unless you have some idea the impedance at the
terminals of the 450 ohm line is near 450 ohms.

The problem with 4:1 baluns is they have restricted operating ranges.
The core is always part of the system, being magnetized by
differential mode (normal transmission line) currents. It is highly
unlikely the feedline would present anywher near 400 ohms or so (the
normal impedance of "450 ohm" ladder lines) to the balun.

Not only that, the coax would be severely mismatched and add to
impedance gyrations as you change bands.

In many cases you'll find the system doesn't work well on some bands.
Using shielded twinlead, or push-pull 75 ohm cables, and a choke balun
at an unbalanced tuner would be less likely to cause problems.

Buck,
Your right, as long as the coax run is short, and you use good
quality coax, it'll work just fine.

Another out-of-the-box method I used several decades ago was to replace a portion of a window with an empty, weather-proofed, and down-sized A/C shell and plexiglass. Built the tuner outside, with controls inside.

You can control condensation with a lamp as a heat source.

Let your ingenuity take over ...

> thoughts?
> Bruce Winkelman AA5CO Tulsa, OK

Bruce, the HF2V works fine on 15 meters. I have both an HF2V ground mounted in my backyard with 15 radials and an R5 vertical mounted a few feet above my house.

Most of the time signals on the two antennas are similar. Sometimes however, dx comes in better on one antenna than the other by several S-units. When this happens, it has always been in favor of the HF2V. The butternut also seems to be a quieter antenna. I dont know if it is the antenna itself or that I'm just picking up more noise from the R5 because it is so much closer to the house

As far as swr is concerned, I have Butternut tuned for 7.1 mhz. With this setting, the swr on 15 meters does not appear to except 1.5:1 across the band.

As a broadcast engineer and ham, I have to ask... do you contact the stations to let them know that they're having a problem, (and give them a chance to correct it) BEFORE "turning them in" to the FCC?

I pride myself on keeping my transmitters "clean" - but problems can crop up with ATU's, antennas, or grounding systems which could lead to an increase in harmonic radiation, without being immediately apparent in the day-to-day transmitter or antenna readings.

If anyone, (ham or not), were to notify me of such a problem with my transmitter, I can assure you that I would correct it immediately - most CE's would. (And, it has been my experience that the majority of radio engineers are hams themselves. That may not be true everywhere - but in this area, I do not know a single engineer who is not also an active amateur).

If you give the station a heads-up to such a problem, and they do nothing about it, then by all means, contact the FCC... but it seems a bit unfair to bring in the commission immediately - without first letting the station's engineering staff know about it.

Of couse. Who wouldn't do it that way, it's faster?

Unfortunately about 2/3 of the stations (even "engineers") think they can't have a problem or don't really care if they fix a problem...or are unreachable.

>If you give the station a heads-up to such a problem, and they do nothing >about it, then by all means, contact the FCC... but it seems a bit unfair to >bring in the commission immediately - without first letting the station's >engineering staff know about it.

What engineering staff? Since the FCC deregulated BC engineering requirements, it's a mess. Most stations have outside engineers, and few of them care what is going on.

The only really responsive station I've even dealt with was a SWBC station in north Georgia. The owner and engineer, who is a Ham, listened...found the problem...built a trap....and had it fixed within a day.

The second most cooperative was a SWBC station in Nashville, that took almost six months to fix a problem that had been going on for two years.

Deregulation was a bad idea.

I have no idea about the antenna you mention, but in the past I have purchased amplified car antennas -- there's a little amplifier in the base of the antenna to amplify the signal -- and that can give you slightly better reception. Check your stereo installer, or go to the web site for Crutchfield car stereos, and see what they have in stock.

We had a problem with a new BC station that was interfering with phones and radios over three towns. The local Radio Shack was getting rich on filters. I called the station several times and could not get ahold of the engineer. I went trough several people and it was surprising how few people that work at radio stations have even a clue how radio works. I finally called in on a call in talk show and explained the problem. That finally got some attention and the next day the station engineer called me to "discuss" the problem. He immediately took the attitude that I did not know what I was talking about, his equipment was fine and if I didn't like it, too bad. I then called the FCC. The problem was fixed within a week after that call. I went well out of my way to let the station resolve the problem and ended up having to go to the FCC anyway.

I don't think so, but best way is to ask the Coast Guard. You
really don't wanna use Marine radio unless your licensed for it,
and there are some 'land' stations. They do come looking for the
unlicensed ones though...

Tom,

A 5/8 wave radiator is fed 1/16 wave from a current maximum. To get 180 degree delay between adjacent current maxima in end fed, collinear 5/8 wave radiators, you need another 3/8 wave delay. I suspect that's what the coils are set up to provide. Something to reflect on -- that 1/16 extra on each end of a 5/8 wave radiator is ONLY there as a delay line itself. It's tolerated because the small amount of radiation it contributes doesn't' hurt the pattern much. Ditto for long, coiled delay lines; they have to be short enough to not mess up the pattern, that's all.

Ham publishing is on the decline. It's rare, for example, that QST even publishes new antenna material (as opposed to the same old stuff)--instead they send it off to the 'compendia'.

The fact is that the web has had a devastating effect to ham publishing, and that people prefer to see antenna stuff on the web than in print. That's not my opinion--nor my preference-- but that's how it is.

A good web site is a valuable focus for getting info out and that's where the emphasis is at this time.

Please lighten up and relax.

Check in your auto parts store. It is used in the installation
of HV rubbers and boots in the 'sparking' system.

Check also in your favorite surplus/discount/discontinued
electronics catalog. I've seen it offered there, as well.

I think I know what Korean station that is, too. But what if the mixing is somewhere else? If I erect a tower that has enough "rusty bolts" in it, I can get mixing products from a number of stations, none of them at fault. I've seen this from bad connections on telephone pole messenger cables, too.

Ditto, of course for telephone interference. Telephones aren't SUPPOSED to pick up radio signals! It's not the transmittors "fault" and there's no rule that says he has to fix someone's telephone.

That's what we get for deregulating things.

The majority of the time when a station has a problem:

1.) I can't contact them for one reason or another (no ID, unlisted
number, no one answers, etc)

2.) They don't have a "staff engineer", or an "engineer" never calls
back.

When I finally reach the "engineer", they usually don't understand the
problem or don't think they could ever have a problem.

One station in north Georgia had their final dipped on the second
harmonic, right on WWV (1250x2)! In three hours of listening, they
never once gave a callsign.

It sure isn't what it used to be when they were regulary inspected and
monitored, and "engineers" used to be licensed!

5/8ths waves have less gain than 1/2 waves when used in collinears,
when the spacing distance from current maxima to current maxima is the
same.

When that extra length is used to move the current peaks apart, you
get some gain when the antenna is longer than obe wavelength overall.

It's like an extended double zepp antenna,

The problem is the phasing sections always radiate, and cause
destrutive interference to the low angle pattern when the antenna is
end-fed. The phase and current ratios are probably almost never right
either.

I have to say I agree with Bart, all the stacked 5/8th end fed
antennas I've seen were no better than 1/4 wl whips. The exception is
they move some radiation up above ground clutter.

Roy Lewallen is quoted as saying. "The currents at the two terminals of an inductor are in phase."

Difficult. because an inductance does not allow the current to change instantaneously. Thus the current must be delayed when passing through an inductance, so the current must lag the voltage, that is, there is a phase shift.

Seems half wave sections, spaced a half wave end to end, would be the way to go.
Make 'em coaxial dipoles with feed for the upper one running through the lower
one.

Lessee... 1.5 waves on 2 meters.. ten feet long!

I'll try it!

Thought this thread was dead. Almost a week ago I observed several commercial omni antennas of multiple elements. All of these with visible parts which I saw consisted of vertical folded dipole elements. Some were arranged back-to-back around a support pipe. Others were distributed vertically in addition to radially and spiraled arround the support pipe.

I suppose all elements were driven in phase and paralleled to bring their combined impedance to 50 ohms or so. Just a guess. This would give good lightning protection too.

I'm sorry, but I was referring to an ideal inductor, the model used in basic circuit analysis. This idealized element has inductance, but zero physical size. For that component, what I said is true. You should be able to confirm this by consulting any basic circuit analysis text. But since you disagree with this, surely you can quantify it by providing an equation relating the currents at the two inductor terminals as a function of inductance. That is, what is the function F such that current out = F(current in)?

I didn't say anything about the voltage across the inductor, or the relationship between the voltage and current. I only said that the current into one terminal has to equal the current out of the other. The voltage across the inductor is, of course, L*di/dt, where i is the current in the inductor. This current is the same at either end.

970. Balun for a all-bander dipole.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 00:00:00 UTC
From: Darryl Wagoner <darryl@shecora.com>
Message-ID: <39A4257E.66EB4770@shecora.com>
Source record: 181907

Greetings,

I picked up a all bander dipole from HRO and found out when I was
setting it up it didn't have
a balun on it. There is 100' of 450 ohm ladder line. HRO said I needed
an 9:1 balun, but
a 4:1 would work as they didn't have 9:1 in stock. I put on a 4:1 from
my G5RV and it
seem to work well from 80-6, but 160 was out of the question. Will
getting a 9:1 balun
correct the problem of not being able to tune 160? The specs says it
goes from 160-10
and didn't say anything about 6.

What should I do? Kept the 4:1 or go for the 9:1?

thanks

At the risk of stating the obvious, the fact that the voltage across
and current through an inductor are out of phase says nothing about the
relative phase of the currents at each terminal.

Or, to put it slightly differently, the voltage induced across an inductor
resists changes to the current at both terminals in an identical fashion,
so the currents at both terminals remain the same at all times. There's
only one voltage across a two terminal inductor so there can't be two
different currents.

Roy Lewallen wrote:

> That is, what is the function F such that
> current out = F(current in)?

The thing that causes some confusion is that the phase between the "applied voltage" and the "through current" involves more than the low frequency inductance of the coil. Because the wire may be a large fraction of a 1/4 wavelength, we should use the "wave equation", in which the phase shift depends on the electrical length as well as its low frequency inductance. The travel time through the wire adds additional phase shift. That is why transmission line inductors have a different reactance vs frequency than lumped coils.

But if we place a voltage *across* the two terminals and measure the *through* current between the two terminals, the current is the same amplitude and phase (relative to the applied "across voltage") at each end. In that respect it is just like any other coil.

Hi Doc

I've lived here 21 years and ALL of my insulated copper radials are still in the same condition as when they were planted. If you remove the insulation, the wire is usually still shiney even.

Now the 2x4 welded wire fabric I put down under the sod 20 years ago is gone from many places, still exists in others but badly rusted.

Funny, a shrub I had planted when I first moved here had died soon afterwards. We went to plant another one only a few weeks ago in the same spot, as I dug down, I expected to hit old roots and god knows what else, instead I came up with one thing. The ball of black plastic wrap that we removed from the original bush, wadded up and stuck to the edge of the hole. It had not deteriorated one iota underground. Above ground UV would have destroyed it completely in less than a year.

I'm aware that this is indeed a problem in many areas. Our particular market (though semi-rural) is unusual in that the majority of CE's (whether staff or contract) are Engineers - some with BSEE degrees, all FCC licensed and with 20+ years experience (on average) - rather than "engineers" who know how to turn a transmitter on and off, and not much else.

But, I certainly am in agreement that if the station takes no corrective action - or refuses to even consider that they may have a problem - that he FCC should be notified.

Correct, You can be land based as a base station to run a marine operation or to communicate with your boat, as the fisherman and charter captains do, but not to converse like a CB Radio with who ever is out there. I thought he was using it to communicate with his boat while they were out on the lake. Often times (unfortunately) some of the small inland lakes and rivers like Corps of Engineers Projects, etc. have pretty relaxed VHF operations because who cares, no one can hear them, but I'd be careful on a major boy of water where marine traffic has protocols.

I've never seen rusty bolts in a tower cause mixing, because the
pressure on the bolts is so high it is virtually impossible to cause
problems. I've seen a few poorly installed guy lines cause problems
from arcing and scratching, or some really slack lines cause problems
with VHF signals mixing.

But that's beside the point. The mixing product was coming from that
station. It DF'ed to there, and the FCC found it was there. They were
told to correct it, and they did.

>from a number of stations, none of them at fault. I've seen this from bad connections on

I have a full wavelength loop for 160m up here, it isn't a very pretty
shape (sort of a twisted squashed square) but it works great on every
band I have tried it on, even 6m
I have it fed with ~ 50 feet of RG58 but if I was to install it again
I would use RG213 to reduce losses on 6m.

I worked Argentina last night using 25 w CW, and a QRP station in NH
USA who was using a G5RV both on 40m

It's not very good for the locals on 40m, but for DX it's the dogs
wotsists.

I have a T2FD (you know, the one with the dummy load in the middle)
and it's better on 40m for local (under about 500Km) contacts.

I have also worked South africa (~10,000 KM) from here (Ireland) using
it on 6m.

> What I'd like is feedback on a couple of questions. First

>means basically a 2 hr. expedition and more money.

I don't know where you live but if there is a farm supply shop near
you, you will find all sorts of handy insulators along with some nifty
springs for taking out the shock of trees moving and a few other bits
in the Electric fence section.
Farm supply shops have all sorts of antenna hardware, they just don't
call it that....

Bits of plastic pipes with holes drilled in it also works

>They're not
>a Home Depot / RS item unless I but another RS SW Ant. Kit.
>Since the wire is insulated, how important are they?? Just to
>counteract line tension by swaying trees??

An insulator won't help with the shock but the big springs they sell
for stretching electric fence across gates etc will work a treat if
fitted between the insulator and the guy rope.

>maybe I'd rather just
>take my chances if that's true.

well you could put one end on a pulley with a weight on it

> Secondly, this loop certainly gets a glowing review from
>the Hndbk. Do you agree with it? Experience with it? To compare,

It will hammer the SH*T out of the66 ft random wire but it may
overload your receiver.

>So this loop is for RX only. Not sure
>how much higher I can get with the loop (especially if I have to
>climb up and tie off insulators). Which is another issue: Even if
>insulators are worth it, would it be better to go for max. alttitude
>of the circuit and just forgo the insulators?

You will want insulators (or a few feet of synthetic rope at a pinch)
if you plan on using it for transmit.

>I have at least two
>possible "routes" to use; the first is a shade over 40M wavelength,
>the 2nd a shade over 80M wavelength. I wanted to go with the

Go for the 80m one, these loops work a teat on all harmonically
related bands (unlike dipoles that only work on odd harmonics.)

>Tom,
>
>I think that larger dia. wire and larger coils DO have higher Q---up to
>a point.

Sure they do. That point is where the self-resonance of the inductor
starts to move down towards the operating frequency.

The optimum form factor of an inductor varies with the end
application.

If you have a loading coil without much capcitance above it, you want
a long slender coil.

If you have a lot of capacitance above the coil and don't need much
reactance, a large coil with an almost 1:1 L/D is better.

Of course if you can use a L/D of almost one, the ESR of the coil and
Q is likely not a major issue anyway.

>Small dia coils with smaller wire and closely spaced turns are
>often lossy.

The only constant thing about an inductor is optimum Q for a given
inductor occurs when turns are spaced one turn diameter.

> When you get over about 4" coil dia., you have passed the
>point where return begins to diminish. Some of those "monster" coils DO
>have high Q, BUT that efficiency works against itself in that they be-
>come so sensitive to their surroundings that one would be just as well
>off with the smaller coils you mentioned.

Not so. I can site common applications where a long slender coil has
more Q than a 4" coil. It all depends on how much reactance you need.

The sensitivity to surroundings is more related to the reactance
required or poor design than the coil Q. That's because the system
resistance is set by ground losses, not inductor ESR.

My highest efficiency mobile antennas are also the broadest bandwidth
antennas I have.

>from where the tap was installed. I see some of these HUGE bugcatchers
>at hamfests and wonder how the operators can get any results at all when
>under way.

I see bugcatchers and other antennas with hats at the base of the whips. I wonder why they bother with a whip at all, if they don't want current to flow into the whip.

It all Ohm's law. In a mobile ground losses swamp-out inductor Q variations. Who cares if inductor ESR is one quarter ohm or two ohms when ground losses add 10 ohms to the system.

It's more what you do wrong that matters, than whether the wire in the coil is 1/4 inch copper tubing or number 12.

985. Verticals and trees

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 00:53:42 UTC
From: Bruce Winkelman <bdwink@home.com>
Message-ID: <qgFo5.87981$oj6.1590142@news1.rdc1.tx.home.com>
Source record: 182002

After 2 brief, disastrous affairs with verticals from GAP and Moseley, I have decided to return to my first vertical love, the Butternut. A tower and beam, however desirable, is not possible at present. Hope to put up a new Butternut, either the HF2V or HF6V before the first of October. My old vertical mounting pipe has moved closer to trees than it was 15 years ago (the trees grew and new ones planted). If I reuse the old pipe mount, the vertical will be within 3 feet of branches on the west side of the yard and within 15 feet of branches to the northeast. Should I worry about the proximity of the trees? What effect will the trees have at HF? Should I just forget about it and have fun? Any advice, suggestions, experiences greatly appreciated.
Bruce Winkelman AA5CO Tulsa, OK

986. Butternut HF2V on 15 meters?

In a previous post, I mentioned installing a new Butternut, either a HF2V or HF6V. Since my 40M dipole works quite well on15M (worked 9G5AP on 20 Aug on the first call on 15 CW), can the HF2V (80-40M) be used on 15M as well? Any thoughts?

995. Vertical radials?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 01:09:59 UTC
From: Bruce Winkelman <bdwink@home.com>
Message-ID: <HvFo5.87984$oj6.1591269@news1.rdc1.tx.home.com>
Source record: 182013

Another vertical question related to my new Butternut installation....
Over the course of my vertical affairs mentioned in a previous post, my backyard has accumulated nearly 1000 ft of copper wire in the thatch. I can easily find the ends to 8 radials recently laid out and the other wire ends are buried and can probably be found with some educated digging nearby. If my memory of installation nearly 15 years ago is sound, most radials were insulated 14G copper wire and I assume that they are reasonably intact and relatively uncorroded. This will probably sound really stupid but...will unattached radials still be beneficial to the vertical or will only the radials attached physically to the feed point of the vertical be "used" and "seen" by the antenna? Thoughts and experience appreciated.
Thanks in advance for any advice.

It will work just fine! You might need to retune the coil a small
amount but you might find it works just the same as it was before the
Butternut capacitor got broken.

> Bruce Winkelman AA5CO Tulsa, OK
I had a Butternut HF2V vertical on a 30 foot pole with the element
going up between tree limbs. Some were as close a 3 feet to the
element. I did guy off the vertical element to keep it from swinging
around in the wind and hitting the tree limbs. I made contacts all over
the place and even DX on 40 and 80 meters. My ground system consisted
of 16 full 1/4 wave radials, 8 for 40 meters and 8 for 80 meters. These
were above ground radials also 30 feet above ground. I used aluminum
electric fence wire and insulators made just for it. I think the ground
system has more effect in performance than trees close by .

1012. Re: What's my Antenna Problem???

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 02:05:19 UTC
From: Bruce Anderson <w1lus@att.net>
Message-ID: <39A2F8F5.5B4540BF@att.net>
Source record: 181830

When two resonant circuits of the same frequency are tightly coupled
they will tend to interact. One of the effects is a slight shifting of the
circuits resonant frequency. Since the other antenna is supposed to be a 10
meter antenna they should not interact. But since they do it probably means
that the 10 meter antenna and it's coax lead resonate on 80 meters and that
is the circuit reacting with your sloper. Try adding a 1/4 wave length of
coax to the 10 meter antenna. I think that may cure the problem.

1014. 5 Band Unknown Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-23 02:14:02 UTC
From: Brenda & Bill Beal <bbeal@home.com>
Message-ID: <39A33395.73C2FFB6@home.com>
Source record: 181832

Recently I posted a couple of questions thinking I have a Hy-gain vertical. An individual advised me to check for part numbers. I have really looked over the whole thing and can find no part numbers. I'm trying to get a fix on what brand and model it might be. It is 5 band (4 trap) antenna about twenty five feet high. There is mix of boots on the traps. Some are a thin black plastic while others are a heavy rubbery plastic (maybe a replacement). The trap insulators are a cream/white plastic, have three interconnected sections, and appear to hav a single screw connecting the outer part to the antenna. There was a capacitive hat that is now lost. It appears that it was mounted on the 20 meter section but that just might be that the clamp was put back there by mistake. The base of the antenna is a 2 in diameter piece of aluminum tube. The active part of the antenna mounts into it with a black plastic or hard rubber section to insulate it. The connector is a UHF connector with a black plastic tube protecting the condutor up to the contact with the active portion.

I am just getting back into ham radio after about 10 years during which this antennas sat around the garage and hung on the fence. I need to make/get a new capcitive hat, attach it in the correct position, and tune this thing up. Any further help appreciated.

Hi Tom,

I think you will find that it dribbles down inside the 9913 and is no
longer sealing *by flooding* anything. The flooded area of the
connector is no longer flooded and the whole thing is a bummer.....

Danny

Don't expect relief by moving to outlying areas, either. Couple years ago relatives lived in Maple Valley (a SEA-TAC 'burb) in a newer subdivision with all underground utilities and services that has a CCR that said nary a word about antennas nor towers. It merely stated that homeowners would not "install additional transmission lines of any type" (!)
I do believe that would take care of it wouldn't it?

Thanks alot for all the replies. Keeping it 2 - 3 inches away from the metal surfaces will not be a problem till I have to enter my 2nd floor Storm Window. Oh well ... perhaps some experimentation is in order. I'm just curious how other hams have handled this. I can't be the only one.... geez I hope not :(73 ---------- John

It's not omnidirectional.
How "directional" it is depends on whether it has additional elements.
Lots of 2M operators use "quagis" with several straight dipole directors out
front and one reflector dipole behind the driven quad.
You can use it without a rotor - if you either don't mind using it just in
one main direction or are using it indoors or in some other way it's convenient
to rotate it by hand.

Dang Bruce

You sound about as bad as meeeeee......

My backyard is almost solid copper, hi hi.....

I've moved antennas all over the yard, and in the process of burying new radials, whenever I hit and old one I strip the insulation, tie to it and spray some enamel on it, actually plasti-dip-your-grip on it.

I did something really really crazy and danged if it didn't work. From the approximate location of where an antenna used to be, I went out about 10 feet and layed a ground radial in a circle, connecting it to each of the original radials, touching only one wire of the old radial bed, which was centered about 25 feet away from the new antenna, made a big enough difference I could see it on an S meter on receive, didn't have any regulars on the air at that time to check the TX side for a difference, besides, I wanted to get the new radials in anyhow before dark, and if I get on the radiola and start ratchetjawing I'de never get those radials in, hi hi.....

I figure, wires cheap, about a penny a foot, and it only takes about 10 minutes per 100 feet to plant the stuff a couple of inches deep, so as always, I go hog wild with radials.

Bruce,

Personally, I'd suggest you "forget about it and have fun". As long as
none of the twigs or leaves actually touch the antenna, the
nearby trees will likely be less critical than the ground system.

I believe you mentioned in another post that you have at least 8 ground
radials, of some reasonable length. The more radials the better; likewise,
the longer the better. But the law of diminishing returns applies here. If
you can hook up more radials, good, but just because you haven't reached
the "optimum" doesn't automatically mean you won't be happy with it. By
the way, I would guess that wires in the ground that aren't electrically
connected to the base of the antenna will probably have much less effect
than the ones that are connected.

You also asked about using an 80/40 antenna on 15. It might not work the
way you expect. Think about a typical trapped antenna. The bottom section
is resonant on the higher band (40 in this case), then there is a trap,
which is generally an L and C in parallel such that the product L*C makes
the trap resonant on the higher band (i.e. very high impedance on that band),
and a top section. On the lower band, the trap is non-resonant and looks
like an inductance in series with the top section. The length of the top
section is just right to make the whole thing resonate on the lower band.
Now, what happens on a higher frequency, say 15m? The trap is not
resonant there. In fact, the designer has a degree of freedom (the L/C
ratio), so the trap's impedance at 15m can be, within limits, whatever
the designer wants. If he had operation in 15m in mind, fine, but if
not, the impedance of the antenna on 15 is unpredictable. If your
antenna doesn't use traps, this argument may not apply, but there is

probably an analogous thought process you can go through to predict how it might behave. Or, of course, you could try mathematical modelling (a computer program like EZNEC).

Now resonance is not necessary. With a reasonably low-loss feeder and a tuner, you may be able to load the thing successfully even on bands where it is far from resonant. However, the radiation pattern may not be what you had hoped. With a vertical antenna electrically longer than 1/4 wavelength, you might be radiating most of your power at higher angles than you want. Again, modelling might be instructive. Another possible side-effect of loading an antenna on a non-design frequency might be excessive voltages or currents in the traps. I have heard that this can be a problem with some commercial multi-band verticals.

My own experience is with a 5-band ground-mounted trap antenna. It's about 15 feet from the house (aluminum siding), 12 feet from a crabapple tree, and 4 feet from a lilac hedge. I keep the branches trimmed back far enough that the wind doesn't bring them into contact with it. I have 32 radials, insulated wire, of various lengths. Some are as long as 70 feet, some as short as 6 feet, but I am now convinced that the distant portions of the long ones are doing very little good; I believe it's the density of radial wires closer in that matters most.

As they say, this antenna radiates equally poorly in all directions. All too often I can hear other hams in the neighbourhood breaking pile-ups when my signal is just too weak to compete. But that doesn't mean I can't enjoy DXing, contesting, and other aspects of ham radio. In fact, I've worked 5BDXCC with this antenna (100 watts, CW).

If you've gotta outperform the other guy, you won't be happy until you have a tower and beam, but if you can live with a restricted level of performance and set your goals accordingly, you can still have fun working the world.

One thing to remember about the silicon RTV compounds is that they are not moisture proof. Moisture can get in and then condense and the only way out is as vapor.

I in 9913 type cables I use the "Dielectric Grease" and fill the connector. That sutff is good, unfortunately it is both difficult to find and expensive.

Typically on the outside I use the "Liquid Electrical Tape" made specifically for Marine installations. It's easy to use, and relatively inexpensive.
Life in the can, once opened is not real good, but I have some connectors (splices) that have been out in the elements over 6 or 7 years now.

I think "we" came up with a simple solution although it requires a bit of work, welding, and painting, as well as a bit of money.

I'm going to add a right triangle to the side of the post that faces the tower.
It will be 3 feet high and 3 feet across the base with 4" I-beam welded in as the hypotenuse which is roughly 4 1/3 feet.

The top two tier of guys will anchor to the top of the upright.
The base will be bolted to the concrete and the back rails of the upright I-beam will be welded to the 5" pipe.

This puts most of the welds in compression mode and puts a very hefty brace against the pull of the guys.

George:

I use Matlab a lot in my work. Paid full price for it and for several of the toolboxes. Many thousands of dollars.

Matlab is basically a "Matrix Laboratory". It is heavily oriented towards vector and matrix operations, and was derived from a set of linear algebra packages.

It has it's own interperted language and can be used to rapidly build and run complex simulations of various kinds. You can build your own models using the vector matrix interpertative language or use lot's of ready made models/simulations from the large variety of application specific toolboxes.

The toolboxes are often developed by third parties and sometimes separately supported and/or supported by the MathWorks. I/we have developed a number of our own toolboxes which we use for the particular kinds of simulations that we do.

All of this MatLab stuff is very expensive at the professional prices. I [my employer] has provided almost $10,000 in Matlab and tools for my/our use. I do a lot of DSP analysis and design and multi-channel communications simulations including cross-talk etc... with Matlab.

It saves me/us a lot of time and money for what we would otherwise have to do a lot of specific lower level programming for probably many manyears and so it is worth it to us in terms of productivity with vector matrix programming.

George, if I was an amateur user, I would go with something else such as SciLab or Ptolemy or RLab, or similar.... which are generally free and which also have a large set of "free-ware" applications available on several WWW sites. Of course many feel that the ultimate math package is Wolfram's Mathematical... everyone to their own taste.

Even if you get the basic Matlab student edition cheap you really need the more expensive toolboxes to do stuff quickly. And by the time you buy all of the toolboxes that you need you are again talking "real money".

MathWorks has a WWW site devoted to the use of Matlab and you can find out more there.

BTW... MathWorks trades on NASDAQ under the symbol MATH.

Although it can be used to do most of the things that you might do with MathSoft's MathCad it is quite different from MathCad and more difficult to learn. I also have MathCad and use it for simpler things that do not require a lot of vector matrix manipulation.

If I was an amateur user I would probably prefer MathCad.

Hope this helps...

Peter

Some of the people I exchange worksheets with use all different versions of the software. I need to use the features in some of the later versions, and I find it a real pain trying to figure out if the person I am sending a worksheet to can run it on their version of Mathcad. Mathsoft had not made this particular problem easy to deal with.

Hello Darryl,

In principle, a 9:1 transforms 450 ohms down to 50 ohms. A 4:1 transforms 450 ohms only down to 113 ohms.

But in practice the impedance looking into the 450-ohm feedline is never anywhere near 450 ohms because the antenna impedance is never a pure resistance of 450 ohms.

So there's no such thing as the correct transformation ratio for a balun. Its main function is to preserve the balance on a balanced line when it's connected to an unbalanced line or equipment.

Its a matter of chance whether the 160m band will become available when changing to a 9:1 balun. If the antenna manufacturer says it will then the odds are in your favour. But you may lose 1 or more of the higher frequency bands.

Before you buy or make a 9:1 balun (a simple job) you may find lengthening or shortening the 450-ohm feedline will be all that is necessary when using the 4:1 balun. Just use the length of the line itself as a transformer.

Your antenna + feedline can be modelled using program DIPOLE1 available from my website. Vary the feedline length and it will tell you whether your feedline needs to be lengthened or shortened. When using the 4:1 balun you would like to see a pure resistance of 4*50 = 200 ohms looking int the 450-ohm feedline.

On the other hand, if the resistance looking into the feedline can be made 50 ohms, all you will need is a 1:1 choke balun which is even easier to make yourself on a 2" diameter ferrite ring. Input resistances anywhere between 37 and 67 ohms or between 150 and 270 ohms will be fine for 160m

You don't say whether you have a tuner or not. That will influence the direction you should proceed in if experiments with feedline length are unsuccessful for 160m.

Is there *any* way in which part or all of the 'earth-ground-resistance' equivalent can be made to appear between the source and vertical radiator, rather than in series with the 'spatial connection' between the radiator and 'earth-ground'?

For years, I have approximated 'earth-ground-resistance' by putting a variable resistor between eg the radial termination point (the 'earth-ground-lead') and the coax braid, and adjusting for 0.5 of the initial current in the 'earth-ground-lead'.

Is the method close enough?

TIA ... 73,

Dave, K3BHJ

Hi,

I have a HF2V still in the box with the TBR160 kit. I have this for sometime now and just wondering how to install it on my rooftop as there are no other place to install it because a lot of houses nearby. I just need an expert advise from you guys who have installed and had been using the Butternut Antenna. Here in the Middle East, most of the houses have flat rooftop. It is used as playground, store area and for drying washed clothes. So I need to install the antenna higher about 10 feet. Now if I install the HF2V using a mast of 10feet, how long are the radials required and does it make any difference if the radials are installed 45 degrees from the feed point down to the roof like guy wires? Please help.

TIA and 73,

Max

Looking at putting up an off center dipole for 10,15,20, and 40 meter as described in the Feb 1996 issue of QST (pg. 65). In my setup it calls for a length of 55ft of 450 ohm ladder line into the shack with connection to the radio through a 1:1 Balun for 15 meter and a 4:1 Balun for 40.20 , 10. Would have to change Baluns for the 2 FREQ ranges. Connection between Balun and radio with short piece of 50 ohm coax
QUESTION How do you provide lighting protection for the ladder line coming into the shack? Doesn't the ladder line have to be grounder before it comes into the shack? Has anyone used this type of antenna? The Carolina Windom 40 uses this type offset dipole but utilizes 10 ft of ladder line with two "special" line isolators.

Hi Roger,
The B'nut 'tuned' radial kit should work well on a flat roof. Yes you
can put the antenna on a 10 ft mast and then droop the radials to the
roof.
If the radials are flat, not drooped, you will experience a slight miss-
match but it should be tolerable.
Otherwise start with 4 radials ~10% longer than 1/4 wave for your
longest wavelength you wish to operate. If you have troublew with the
shorter xavelengths then you may need 4 per band... (4 for 40 for 80
and 4 for 160) as the roof is flat it should be ez to play around with.

Although I have seen this when using YO, the bandwidth over which the clean
rear pattern remains is very narrow and usually shows high sensitivity to any
changes in spacing, length etc.

What do you use for coax tom?
I have to basically replace all mine as the new runs are longer than the
current ones (over all about 175 to 200 feet from rig to antennas).

I'm thinking about using the new Times Wire coax for the VHF and UHF
antennas.

There are a number of silicon greases.
The only ones with which I'm familiar, are the DC4 and DC5 Dielectric
Greases made by Dow Corning.
> It's also used for lubricating O-rings, so some industry which would
> have a need to do this should also have a source.

Aviation and automotive would be two fields that use it.
I used to use it to water proof ignitions, but keep it away from the actual
HV spark, or you get sand. More properly SIO2

I'd think it would be cheaper at automotive stores than aviation repair
shops.

I used to get mine at the company store and bought a whole carton just
before I retired. (They've since closed the company store) I used to get
the electronic grade RTVs there as well.

Actually it doesn't take much to do that either... Unless you have a lot of
connectors.

BTW, I've only used the stuff up through 2 meters so I don't know how it'd
stand up to UHf and beyond.

> the natenna. THe coax is taped to the mast below the antenna to take the
> strain. There is enough slack (loop) in the coax for the mast-antenna
> assembly to move full circle.

I use the guy bracket about a foot below the top of the tower so I use a
cable clamp at the corner hole in the flat top, make one full turn around
the mast (with lots of slack) above the thrust bearing and then tape it down
to the mast as Bill has done.

The tribander goes about one to two feet above the top of the tower, the 6
meter antenna about 15 feet above that and the 2-meter/44 antennas about 12
feet above that and the TV antenna about 8 feet above them. I have to
remember not to use the TV antenna when on 6, or 2 and use a shorting relay
for the preamp at the antenna.

All cables from the top of the tower up have to be flexible.
Actually the TV feed line will go up the *inside* of the mast and the
flexible coil will be around the rotor.

If your antenna is right at the top of the hollow mast there is no real
reason not to go up the inside, but be careful of sharp edges. Remember to
that it might be well to put a metal cap over the top as that is the highest
point of the system.

I'd cut a grove in the side of the pipe at the top, or drill and deburr a
hole *just* below the top for the coax. Then throuroughly seal it in place
using Silistac RTV, or equivelant. Doesn't matter what it smells like in
this case and the stuff that smells like vinegar is stronger than the stuff
for electronics.

This has the advantage that any water trying to get into the cable has to go
up hill right at the start so if there are no horizontal connectors outdoors
I'd only seal them on the outside with the liquid electrical tape, or give

them a good weather proof coating of something, but put nothing inside.

Actually if you don't have any long runs to the antennas it might be easier to run as many as two or three up through the mast instead of going up the outside.

As for inside, or outside the tower, I use what ever is handy at the time.

My old tower has been struck three times in the last 12-15 years and the new tower aparently got one hit yesterday, but with no damage to anything that I've been able to find. Course I don't have much up there yet.

Even in relativly good soil, the RF ceases to know that the ground rod is
there for much more than a foot.

Many years ago, not too long after getting my license, I had my station set
up in the basement. The details are a *bit* foggy as that was nearly 40
years ago, but near as I recall:

I was using the copper pipe in the heating system as a ground and it seemed
to be working quite well.

I was closing down and as there were supposed to be some storms that night.
I grounded the coax center connector from a jumper to the rig to a handy
point on the copper pipe as well. The signals on 20 didn't get any weaker.

So...I thought ...why not and keyed up the old HT37 and called a station
that had been calling CQ. He came right back.

As I recall the distance was around 600 - 800 miles so it was rather short
hop, but signals were strong..

We lived on a shallow sandy hill that was maybe 8 feet above the average of
the flat land around us and with the basement walls the heating pipes were
probably a little over 2 feet above the surface. So I had an antenna about
10 feet above the average surface level.

It had to be pure luck that I hit the proper connection point, but it did
work. Using the "facalities" while transmitting would probably not have
been a real good idea. <:-))

1056. Re: why do pagers emit radio frequencies?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-26 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39A819DD.F8DDA048@eznec.com>
Source record: 181724
Cross-posted to: comp.dcom.telecom.tech,rec.radio.amateur.antenna

I don't think the general population has any concept of the nature of radio frequency energy, let alone the distinction between the power levels involved in transmitting and receiving. Given that lack of background knowledge, I suppose it's a reasonable concern. At least, not a surprising one.

To the concerned person: The power being radiated by your pager is somewhere around a millionth to a billionth the amount of power radiated from a transmitting cellular phone. In any urban area (and most rural ones in the U.S. at least), your body is constantly being struck by radio waves which are many times stronger than the signal from your pager. The difference your pager makes in the total background of energy striking your body is miniscule.

Source record: 181725

I have a problem with declaring an antenna to "work". This nicely separates all antennas into binary pigeonholes, ones that "work" and ones that don't. It leaves no room for the vast continuum of performance parameters that distinguish the many types of antennas. Using this simplified sorting method, we no longer have to concern ourselves with the mundane details of pattern, gain, directivity, or other distractions.

If the object is radiating a signal which can be heard by someone, somewhere, bed springs "work". Buried antennas "work". Light bulbs "work". Most dummy loads "work". In fact, you have to work really hard to make an "antenna" that doesn't "work".

Indeed, antennas low to the ground not only "work", but are among the very best for NVIS communication. In contrast, higher antennas work much better for long range communication, and much worse for NVIS.

>alert selection for.

Any device that has digital circuits will generate a lot of
radio frequency signals. The pulses involved in digital signals
are guaranteed to be full of such RF (each squarewave pulse
consists of the frequency of that pulse, plus every odd harmonic
of it at gradually decreasing amplitudes). Typically that
results in noise that can be heard on an AM radio. You will
find the same kind of noise if you put a radio up close to a
computer, for example.

I doubt that the energy levels coming from either a walkman or a
pager are a health threat. Or at least not from the radio
frequency energy they emit (the walkman also emits some RF,
BTW). Either device might be a danger if you start paying any
attention to the *sound* energy that can come from them though!

I'd recommend ignoring them both entirely, which is usually best
accomplished by leaving them in a desk drawer somewhere...

Sure, in one test you report a difference of "ten over nine" on a six foot high antenna on 40 meters and S8 for an antenna several inches above ground.

None of us know how accurate that test, or any of the tests are, but that certainly could be true. That might be an actual ten dB difference or a 20 dB difference, either way it's a big difference!

However, even the stronger six-foot-high antenna would benefit several dB from a good ground screen and more height yet...even for NVIS.

There's no question almost anything will radiate and allow contacts to be made, the question is always "is it as good as I can reasonably do?"

In einer Entfernung von ca. 50 km Luftlinie strahlt ein ï¿½uï¿½erst hï¿½renwerter Radiosender
(Funradio) in vertikaler Polarisation ab. Im Auto kann ich diesen mehr oder weniger recht
gut empfangen, bei meiner Heimanlage ist dies nicht so leicht zu realisieren.
Dzt. habe ich eine 7-Element UKW Antenne der Fa.Wittenberg in horizontaler Lage dorthin
ausgerichtet. Das Ergebnis ist nicht wirklich befriedigend (Funradio 40 dB, die lokalen Sender
kommen weiter mit 78 dB), d.h. im Stereo-Betrieb ist da noch immer ein leichtes Rauschen.
Der nï¿½chste Schritt wï¿½re jetzt eine 90 Grad Drehung der Antenne, was in Anbetracht der
gegebenen Verhï¿½ltnisse recht aufwendig aber machbar wï¿½re.
Hat jmd. Erfahrung und kann sagen, ob das etwas bringen kï¿½nnte oder ist das bei UKW mit
der Polarisation nicht so heikel?

Chuck--

Please tell everyone how your this pursuit against the allegedly bogus post gone under the 'w8ji@aol.com' screenname is going.

I have a minor curiosity in who is the forger.

It is obviously not me.

Not a peep out of AOL, which is logical considering I have nothing to do with it. And I am still here. Can't imagine why I shouldn't or wouldn't be....

I hope these bogus accusations--and I believe this is the 5th or sixth in two weeks, will stop. It is annoying and injurious to my reputation.

Chuck O'Neal has stated that he has notified AOL about these alleged forgeries, and I think that is a great move. What he has NOT told you is that if he has received ANY response at all, it certainly does NOT invoke me.

Best Regards,

Chip N1IR

Randy,
Spark gap lightning arrestors are totally worthless. For a
lightning arrestor to be effectove it has to be very fast acting.
'Spark gap' arrestors are about as slow as one can be, don't
bother.
The simplest/easiest means of protecting your self is to just
disconnect the antenna. A couple of 'aligator' clips, or a knife-
switch work well, and you won't 'screw up' your antenna.

your walkman undoubtedly radiates some rf also. unless extremely well shielded almost all electronic devices (even receivers) radiate something. most devices have to pass an fcc certification to make sure they don't radiate enough to interfer with other devices, but at very close range you will still be able to detect it.

Hmm, is their a type of attestor that you would recommend. I was looking at the Cushcraft LAC-4. We used an arrestoer(not sure the brand) on our club repeater and about two years ago it look a direct strike. The antenna was turned into tooth picks, but all the gear below the arrestor was untouched. My be we just had good luck. Do you classify all arrestors the same way??

Thanks for the reply.

Spark gap arrestors aren't slow. They are just as fast as any other scheme, maybe faster than some methods.

Yep, disconnect the antenna. You won't be operating anyway during a storm.

Wayne:

20 feet is about 7 meters or 1/3 wavelength at 20 meters, which is quite a bit removed from "ground".

Always keep in mind that distance along a conductor/transmission line as measured in wavelength is a non-negligible factor when dealing with RF frequencies.

And so... even if you had a "perfect" ground 20 feet away, when your transmitter looks at it through 20 feet of wire it is appears to be an entirely different impedance/object from the "perfect" ground 20 feet away on the other end of the ground wire.

From the transmitter viewpoint it is sort of like you trying to read perfect number 10 font type text through the bottom of a coke bottle. You know it's perfect but it doesn't look like that to you.

That being said, your "perfect" ground 20 feet away on the ground wire is likely not very perfect either and so...

A better analogy would be you trying to read the scriblling of a 4 year old's hand printing throught the bottom of a coke bottle.

And so... your, 20feet of wire connected to a ground rod, grounding scheme will do something at RF, who knows what? And... may result in acceptable ham station performance in terms of snagging some QSO's but... it probably won't be even a close approximation to a good RF ground!

Wayne, it would be difficult to provide a complete education on RF transmission line physics and RF system grounding here on newsgroup postings, and so... you need to get some study materials and do some experimenting and keep asking questions on the NG to get a good understanding of this area of the radio arts.

If you are "in a hurry" I would suggest finding a local "expert" ham to help you. If you have time to "mess around", then get some good books, some test equipment, ask questions on the NG and keep experimenting, after a while, you too will be an expert on RF grounds.

Best,

Peter K1PO

Robert,
If I understand you correctly, you are wondering if changing
polarization will improve the received signal. There is about
a 30db difference in receive strength between vertical and horizontal
polarization. If the transmitted signal is vertically polarized, best
signal will be from a vertically polarized antenna.

I can't think of the manufacturor, but the arrestors that are
most effective use a 'gas discharge' cartridge. Once they 'blow',
the cartridge needs to be replaced. There are several manufacturors
who make them, I'm just drawing a 'blank'...

To clarfiy, I cannot get the antenna outside due to restrictions of the
university that I attend. My antenna must be indoors and a local ham
told me that if I have a twin lead j-pole in cpvc or pvc that it would
work better then how it is now. He also stated that it had to be built
in a certain way. I havn't been able to find the site and was hoping
that some wone knew where it was or had the plans already. Thanks.

I tried it with my Casio watch and I get a loud tone. I also tried it using my tone tracer and got pretty much the same thing. I read somewhere that there's a high voltage upconverter in there, but it must be small and light since it's not obvious from the outside that there's any transformer or whatever in there.

One thing is for certain: Indiglo lights wear down the battery fast. I don't use it, and I don't want it to go off at any time. I tried to turn it off in one of the menues, but it still activates when I press the light button. I hate that, because I see it go off occasionally when I bump my wrist into something. Dammit, I wish it could be disabled completely.

First, thank you for your replies.

I didnot write the original message in English because these technical terms are very difficult for a native German speaker.

That radio station is FUNRADIO (www.funradio.sk) and the antenna is made by WITTENBERG.

Now I have another question. What do you think will happen with the local radio

signals when I turn the antenna 90 degrees? Now I can receive them with 72 to 78 dB, a minus of 30 dB would be too much.

Robert

You must not take watches apart much ;>) There's just a single SM
transistor driving an inductive kick circuit. A SM cap on the base
sets the "on" time. The tone slowly changes on mine as the cap
discharges. Lots of room on those tiny boards, considering.

They make nice backlights for small meters when you have a decent
power supply available. But shield it, or else. Very noisy.

You got that right. Just open the case and carefully remove the tiny
bit of metal that completes the circuit when you push the button. Then
superglue the button in place in the case. Wait for it to set
completely before reassembly.

Alternatively, shave/grind the button down so it won't activate
accidentally.

If you were in steel mesh, I doubt the vertical would "actually" work much better than the other one as far as total rf escaping the room, but it would appear to in practice because most FM repeaters,simplex etc is vertically polorized as a rule. This can mean 20 db or so difference. So it would work better than the present one, but still would be a whole lot better outside same as the other one. A twin lead dipole even outside is not the greatest FM antenna. What I do here is just hang a 1/4 wave ground plane from the ceiling. Easy to make in minutes with 5 pieces of 19 inch stiff wire or rod and a so-239 coax connector. Fed with a short amount of coax.To hang it up I tie fishing line to the tip of the radiator and hang from the ceiling with a thumbtack or nail. With whatever you use, walk around the room trying different places before you pick the final spot. You will likely find places much better than others. In a normal wood house with not too much metal around, an indoor antenna can work real well. MK

Bill,
With metal mesh in the walls of your dorm, your in effect operating inside of a Faradaqy cage. Reception will not be the 'best' in the world no matter what antenna you use. One suggestion would be to hang an antenna in the window. One way of doing this on VHF is to use 'burglar alarm' tape for the antenna elements. A couple of the connectors used with this tape make handy connection points for the feed line, and if/when you move, simply peel off the tape.
'Doc
PS - Wouldn't run more than 400-500 watts through it though...

I thought about grinding the button down. But I tried to 'modify' the rubber button on my remote control and I had one helluva time. I used a sharp drill without success and tried a knife, and it didn't do anywhere near as much damage as I wanted. I dunno what they use to make those buttons, but they're hard to work with, not so much tough as they are flexible and tend to give instead of be cut up. All I was trying to do was put a dimple in the middle of the button so I could recognize it by feel instead of having to turn the light on. Jeez, you'd think they would think of such things! Also if I go a little too deep, the whole button top might come off, exposing the innards and ruining the water seal. I may just fill it up with superglue.

BTW, I've got a couple casios that I've 'worn out', mostly the keypad has fallen off and beat up on the outside. But they still work, and I put new batteries in one and I hung it next to my kenwood HF receiver to keep time when I monitor WWV for the time signals. They still work okay, so why tear them apart? I did buy a Times Indiglo traveling alarm clock for ten bucks and I pulled it apart when I got it home, to see what was inside, then put it back together. I don't remember much other than the thing was jury rigged inside to correct some major booboos they made in the original PC board. It used two AAA cells to power it, so it's no big deal to wear them down and replace them.

> Mark L. Fergerson

BTW, It's alright for the indiglo to glow in the dark, but if _you_ start to glow in the dark, then there's a problem!

Cory,

Are you talking abourt CB antennas, that are mostly made to sell
rather than to work?

5/8 wl of wire on a 6 foot whip radiates like a 6 foot long antenna,
or worse. It will be a small amount worse than a full size 1/4 whip.
Winding more wire than necessary on it to make it resonant makes iut
WORSE, not better.

A base loaded antenna will be a tiny bit worse than a full size 1/4 wl
whip, all other things equal.

All that crap is just a sales gimmick, like the little hoops CB'ers
buy and mount near the bottom of the antennas.

Source record: 181684

OK, I've ordered me a new 2 meter mobile radio, should be here next week. In the meantime, I have to decide what kind of antenna to get to use with it.

I have looked at three that I am pondering. The first is a Yagi. Good gain (13db),
but very directional from what I understand. As I recall, runs about 110 for the one I saw.

The next is a dedicated 2 meter vertical antenna. At around 99 bucks a good deal and is omni-directional, and had about 6 db gain.

Finally, there is the multiband discone antenna RS sells for 60 bucks. Best price, but since it's a multiband it is sure to have some performance degradation at 2m versus an antenna designed for 2m. However, when I finally upgrade to general I'll already have an antenna up.

Most of the repeaters are north and west of my house, however there are a few south and east I'd like to try as well, which makes me undecided about the Yagi. Is it worth it to go out and spin it around when I want to make contacts in a different direction, or is the extra 7 db worth it?

Any thoughts?

>vertical antenna.
>
There are real advantages to using a folded monopole, especially at MF,
but whenever the antenna is electrically short.
Folding the antenna, changes the sign of the input reactance, and the
positive input reactance of a short monopole allows the use of a
capacitor to bring the system to resonance.
Capacitors generally have lower loss than inductors when used to match
an electrically short antenna.
The impedance transformation obtained by using the folded system also
reduces the losses in the antenna tuning unit.
Finally, the fold wires form a cage around the mast, which results in an
increase in effective radiator diameter.
The result is a wider operational bandwidth.
The folded monopole will not reduce ground losses, and is not a
guaranteed protection against lightening strikes, but it will usually
outperform an equivalent base insulated mast in efficiency, bandwidth
and inherent resistance to lightening induced damage.

Robert,

Your English is no doubt better than my German.

It might be easier for you to use two antennas, one horizontal, for one station (if that makes it readable), and one vertically polarized, for the other. I seem to recall seeing that kind of thing when I was in Germany in the 1980's and earlier.

How far away are the repeaters? Is your location high and clear
or down in a hole?

I wouldn't buy anything until I got the radio. I'd put a 1/4 whip made
out of a wire into a pl-259 and see which repeaters I could hit.

Next step would be to make a 1/4 wave ground plane from an SO-239
and some wire and get that high & clear. If I was way off with that from
hitting the repeaters I wanted to hit, I'd get the yagi & a rotor. If there
was
just a little noise, I'd get the 2m vertical.

Much of the fun of ham radio is making do with what you have. Most of
the learning comes from that as well. Don't be too quick to spend your
money when there are low cost/no cost alternatives. Take the money
you save on an antenna and buy a vhf swr meter. You'll have a tool,
have learned something and be more self-sufficient.

73,
Tom - N1MM

rsm wrote:

> Does anything really work very well?

Not really! Mobile operation on 80 is a series of compromises.

To avoid ground losses, you need an antenna mounted on top pf the vehicle. But there is a height limit of 13 feet 6 inches on most roads (and there ARE lower objects over many roads!) so if your vehicle is, say 5 feet tall, you can only use 8 1/2 feet for antenna.

Then you need a low-loss coil, A big Bugcatcher coil works pretty well, the bigger the better, too, except for the fact that you want it up a few feet in the air and it's hard to hold it there against inertia and wind. Things get easier if you can use a top-hat instead of a whip, as the coil can be moved higher. But all the problems of mounting a coil get worse the higher it goes. The top-hat should not be TOO close to the coil; you want its capacitance to be versus ground, not the coil turns. I have used a top hat up to 7 feet across, made from plumbing fittings and replacement auto-antenna whips from Radio Shack. This sort of antenna ends up needing either a REALLY heavy mast and mount, or guys. Or both!

But if you DO put an antenna like that on your car's roof, you daren't put anything else under it, as even a moderately sized VHF antenna will change the tuning of the top hat as the VHF whip sways in the wind.

In the end, you use what you can come up with. My home brewing experiments with Bug-Catchers led to a monster mag-mount. I mean to try a Screwdriver on it, with about a 3 to 5 foot top hat. The little white car already has enough dents to look like a golf ball, so if five, five inch magnets on an 26 inch triangular base aren't enough, I can always shrug it off to experience and start drilling.

Oh yes, you don't get a guaranteed 13 1/2 feet of clearance, though that's the Federal standard. I had a tree branch lift my antenna AND mount off the roof one night and smash a rear-quarter window. Saw blades on the next one!

Good luck!

1097. A note to all about my fractenna question.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-27 00:00:00 UTC
From: Wayne Grauel <wgvideo@attglobal.net>
Message-ID: <39A999D9.720DD6C7@attglobal.net>
Source record: 181689

I just want to address Chip and the others on the NG briefly.

First, I'm relatively new, so I asked an intelligent question about what was fractenna, One gentleman came back with a very intelligent reply...one of the regulars and not one of the Fractenna group (as was explained), but gave me a very clear understanding of what and not who, a Fractenna was, and said nothing bad about him or them. this pretty much cleared things up for me.

You will notice I didn't really post anymore about it.

A week or so later I saw a link to the Fractenna site so I looked at it and from my perspective of not knowing a whole lot about the concept (or antenna theory in any great depth) , It looked fascinating. I asked some intelligent questions, like what holds it together under snow, ice (only to realize that I was looking at the little two meter version)

Here is my problem right now. I seemed to have generated quite a stir for a simple little question and now I know why.

It seems like Fractenna gets a lot of abuse from the group... and as I see it, any ASSHOLE who re-posts a personal (partial) email completely out of context deserves everything he gets. Chip, don't give me any of your bullshit that the email was not marked confidential. That's the biggest bunch of crap I've ever heard. So what are you, an engineer or a lawyer. If you're not a lawyer, may you should study to be one. It will save you a ton of money for all of the people you need to sue for liable and patent infringements and God knows what else.

To set the record straight, I also noted that most of the people on the NG are way above my head in their level of engineering, and the degree of knowledge and theory each of you brings to the table. In other words. what I'm saying is You all know a heck of a lot more than I do, why would I judge?

I truthfully thought that Fractenna was some kind of joke or someone posting stuff about a fractenna as a troll.

From the outside looking in, it would not be hard to misjudge what one is reading.

So, let it be clear, I have nothing against anyone out there, I was just asking a simple question.

When you walk into this NG you see all this Fractenna stuff and all these posts about suing, liable, etc., etc. and you so have to wonder what the heck is going on because there's no threat of lawsuits, on any

other threads as you guys discuss in great depth antenna theory.

I've been on other newsgroups, and sometimes there is someone out there with no interest in the group (other than to stir up trouble) making all kinds of ridiculous statements and antagonizing the others in the group. these people are called trolls.

This is how it started... I loffed into the NG and rather than take about 1250 posts, I selected 100. After downloading a hundred topics guess what I was... HUGE threads with all these posts and people yelling and someone else out there threatening to sue everyone (not mentioning any names here). From my perspective it looked to me like that's what this guy calling himself Fractenna seemed to be doing. Keep in mind, this is strictly from the surface and how it appeared to me as I downloaded the first group of messages from the NG (yes, i was on a long time ago a couple of times, but there wasn't any Fractenna stuff going around). And obviously... this is why I asked?

So, If my intentions or the nature of my question wasn't clear, I hope it is now. Sorry for all the trouble I've caused!

Wayne

Go ahead Chip... sue me!

It all depends on how well you wan't it to work. Think
quantitatively/numerically.

If you go up to a height which will just allow you to pass
under bridges, with a helical antenna on the roof of your
vehicle on 80m you should be able to put out a signal which
is only 2 or 3 S-units less than a 1/2-wave dipole at a
height of 60 feet.

By 'helical' I mean a winding on a 2" diameter former,
space-winding using 10 awg enamelled wire or larger,
extending for 3/4 of the overall height. Top 1/4 is the
tuning rod. Very narrow bandwidth - only a few kHz.

Such an antenna does surprisingly well on 160m too. 60 miles
via groundwave at noon. If you try hard, trans-atlantic via
the F-layer during long, dark, quiet, winter nights using
400 watts.

Take a look at G3YXM's website. (Sorry. I can't find his
url).

You have to be careful there.

The differential mode impedance is inductive, and the hairpin monopole can be matched with capacitors, but it is NOT more efficient than a conventional monopole of the same height. As a matter of fact, it is less efficient unless great care is taken to minimize conductor resistance in the antenna.

The reason for the lack of effficiency is the hairpin monopole (an electrically short folded monopole) has high circulating currents that involve the entire radiator. The VAR power is very high, worse than in a conventional inductor loaded antenna.

So while you decrease loss in the loading inductance by "removing it" and using a higher Q lower ESR capacitor, you add a new loss mechanism that involves even more conductor resistance and even higher circulating currents.

The only real advantage of a hairpin monopole is it allows two capacitors to be adjusted to move the antenna over a very wide frequency range. If large diameter high conductivity conductors are used in conjunction with vacuum capacitors, efficiency becomes about the same as a base loaded system.

>Capacitors generally have lower loss than inductors when used to match
>an electrically short antenna.
>The impedance transformation obtained by using the folded system also
>reduces the losses in the antenna tuning unit.
>Finally, the fold wires form a cage around the mast, which results in an

>The result is a wider operational bandwidth.

The hairpin monopole has very restricted BW on frequencies where the radiator is a small fraction of a wavelength long. That is because VAR power is so high. Matching losses are less, if you don't consider circulating currents in the antenna part of "matching losses". If you

do consider I^2 R conductor losses in the antenna as matching losses (they are certainly real losses) then you have to consider them antenna losses.

On 3 MHz, some military hairpin monopoles are made from brass so they are "de-Qed" enough to handle a SSB voice channel!

Guyton,

See there, we CAN have fun on the newsgroup without getting mad! LOL!
I do remember the days when having a multitude of antennas was the only
way. My screwdriver took care of 3 of them (75M, 10M, and 6M).

BTW, I had a new experience today. I was travelling in the mobile and
one of the guys suggested we QSY up to 29.000 MHZ and do a little AM
work. Before you know it we had several stations on AM, including
California (I'm in NC), for a nice QSO. It was FUN. I hadn't really
tried my IC706 on AM before, but everybody said it sounded fine.

Actually there is a difference Reg. Some CB antenna manufacturers wind
so much wire on the fiberglass whip that is actuall develops out-of-
phase current areas.

That places a null at ground level, and most other angles. It also
adds needless resistive losses.

CBers buy the antennas, because they "have more wire inside".

They remind me of fractal antennas.

Ground losses are about the same on 80 meters no matter where you
mount the antenna. The vehicle, unless you have a Mack truck, is too
small in terms of wavelength to have distributed impedance problems.

Mounting up high is sometimes better because it keeps the electric
field of the antenna above the loading coil further away from
sheetmetal.

Just how do you plan on running either of the antennas mobile ? Go with
the vertical as you will have a hard time tracking the repeaters with a
beamwhile mobile.

>> that.
>>
>what would you suggest? I need help.

I can suggest something along the lines of what I am using....

I have installed (just outside the shack) a ground rod. To this rod I
have attached about 14 radial wires. These wires vary in length from
as short as about 12 feet to one wire which is over 70 feet long.
These wires are spread out in a fan shape over 180ï¿½. The wires are
laid below the surface of the ground by about 2-3 inches.
Additionally, to the ground rod I have attached a 3-4 foot length of ï¿½
inch copper tubing which is brought inside the shack were all the
equipment is connected to it.

This has served well.

Remember RF doesn't penetrate too far into the soil and by having a
lot of radial wires you will provide a good path to ground for RF.

There may be better system than what I am using but I am happy with
it.

I hope this helps.. If not email me.

A little mobile whip or hombrew 1/4-wave ground plane fed with about
25 watts will probably hit most, if not all, repeaters within a 20-30
mile radius, if not further out, especially if the repeater antennas
are of a decent height. Start with the least antenna you need. You
don't really require a beam for repeaters, unless you're trying to hit
some very distant city.

For 80 and 160, I've found a shorter antenna, mounted on the roof, works better than a longer one with the same tip height, frame mounted. I've seen this ascribed to concentration of ground current near the feed point, which does sound logical. It is in no way to be ascribed to the perfomance of the car's body as an efficient counterpoise, the car being much too small for that. But even a sheet steel roof has less resistance than the same area of asphalt or concrete roadway. Also, avoiding vertical parts of the car does reduce cancellation of radiation by nearby opposing currents.

I've always considered all email to be private and confidential unless the sender specifically gives me permission to reveal it, and feel that this is simply common courtesy and considerations for others. I always have, and always will, adhere to this standard, as I believe most others do. But I've come to find out that other standards prevail. Chip has stated quite a number of times that he considers it acceptable to publicly post the contents of any email not specifically marked "private" or "confidential", and has posted a number of email messages sent to him. Regular readers of this newsgroup should be aware of his policy, but newcomers are blindsided from time to time. Does anyone know if this is a general practice, or if it is, as I hope, unusual?

Reg:

Yes, of course, radiation was the user's intention.

He just didn't think the 20 feet of ground wire was going to be doing the radiation, heh, heh.

Speaking of good grounds and ground leads, I once had an abode in Miami, FL near where the International Ground comes ashore from Europe.

As you know, the continents are all hooked up together to the International Ground by a series of undersea cables. Lord Kelvin pioneered this concept, around the same time as the time zone system was set up at the turn of the prior century. I think it was Oliver Heaviside who perfected the International Ground system.

Well a few years ago I lived in South Miami, Florida, just a couple of blocks from Dinner Key where the International Ground terminates in America.

One night I snuck over and hooked my station ground up to that big International Ground cable. It's 0000 guage copper, big sucker...

My ground lead was about 1200 feet long since I was living about a half a block from Dinner Key, and I had to quietly drill a small hole in the side of the 0000 guage Big Ground Wire and tap it to take a small copper screw and ground lug for my ground lead.

Wow!!!

What an effect that had. At my QTH, European signals jumped right up out of the noise by at least 20 dB.

But before morning the US Coast Guard discovered my ground tap on the International Ground and removed it under threat of me doing time in the brig.

I wonder if any other hams have had the good luck to hook their station ground up to the International Ground grid?

Regards,

Peter K1PO

Thanks Dale, since this antenna is not very good at HF I think it's out.
I'll think about the others.

I have plans and parts to build some antennas, but have been having a real problem with my time lately. I've been working six days a week, then helping the wife with 21 month old and 7 week old daughters, plus trying to find time to study for my general so I've had zero spare time. That's why I was looking to buy rather than build right now.

Jeffery,

I currently have 8 acres of land and live out in the country in an area with none of those housing covenants, so I don't have to be discrete. <GRIN> (One of the reasons I bought the house was so I could put up antennas!)

However, the mag-mount does give me the idea of taking one of my spare mag mounts and attaching it to the side of the house. At any rate, I'll try it and see how I get out. It might do until I have time to build something myself. Then, as someone suggested, I can put the money towards a good meter or something.

Thanks to all of you who replied!

Pirates always take risks. These include doing inadvertant (and obviously unauthorized)marketing for the legitimate IP holder.

Ultimately, after doing the prototyping, and manufacturing and perhaps even shipping, they end up 'up the creek' with the pirated product sealed in some warehouse and ultimately destroyed. Or worse--they have some customers using the pirated product (while patent pending) with no follow-up source.

Goodbye customer!

The pager has an oscillator in it which drives the microprocessor as
well as provides for the generation of Intermediate Frequencies within
the pager for demodulation and frequency tuning purposes. It is
extremely low power, which is why you don't hear anything until your
walkman gets very, very close to the unit.

Your walkman is designed to pick up signals measuring in the range of
a millionth of a volt. (0.000001)

BTW - your walkman has an oscillator in it too, just on a different
frequency as not to interfere with itself. You have nothing to be
concerned about regarding your health. You get far more radiation from
the sun.

Harry,
You need to go back a ways, like to, 1974!
The ARRL Antenna Handbook published an artical:
"A YAGI ANTENNA WITH HELICALLY WOUND ELEMENTS"
It was a 2 element mon-bander for 40 M. 18 ft elements spaced 15'8"
apart. The design includes a matching xformer.
Also in the same handbook is:
"SHORT HELICALLY WOUND VERTICAL ANTENNAS"
I have built a couple of these for mobile use (10M) and they work quite
well. (Most HF mobile antennas are helical).

Perhaps the ARRL can send you copies of these.... If not e-mail me I
maybe able to e-mail you images of the pages.

First congrats on the General...
Second... you can not beat a ladder (450 ohm) line fed dipole for SIMPLE multi-band use. Put up as much wire as you can, as high as you can. No need to make it for any one band. (Making it resonant on a band be more of a hinderance than a help) If you can get it over 100 feet long you will be able to work 80. If you are restricted in length you can tie the two ends of the feed line together at the tuner and work it as a vertical with a BIG cap hat for the lower band(s).
And, you didn't mention 30,17 or 12! All will be accessible thru this type of antenna!
As mentioned if you have trouble tuning a band add a little ladder line... it should help. There will be a conbinmation of antenna / feed line length that will work on all bands.
Feed it with ladder line thru a balun (4:1 is OK... if one is not in ur tuner roll your own... very easy to do!)then into a good tuner. Once you have the tuner settings for each band you will be able to go right to them....
Enjoy

My experience tends to disargree with:

> The ground system will work better in the air than an in ground
> radial system.

I have found, from working with my B'nut both elevated and on the
ground, that:
If you can not get the antenna high enough to "decouple" it from the
ground, performance will be degraded. Minimum height is 1/4 wavelength.
For 20M and shorter this is easy. But for 80, 40 and 30M a vertical
will work MUCH better on the ground, with a radial system, than it will
at a low height such as 20 feet!
I am not saying it won't work, it will radiate, but the B'nut on the
ground with 12 radials will do MUCH better than if it is mounted at 26
feet with 4 radials (the B'nut radial kit) on 30, 40 and 80M!
...
If you are below 1/4 wave in height... think about ground mounting.

Source record: 181763

Hello to the group,
I have built and tuned one of the above antennas, but for some reason it doesn't perform the way it should. I was told that the building that I now reside in was built with a grounded steel mesh under the plaster. I have no way of getting the antenna outdoors and in the "clear." A local ham informed me that there are plans for an indoor twin lead j-pole that goes inside of a pvc or cpvc pipe and should work in my room without a problem. Would anyone know where I can find that site, or have the plans available? Thanks for all the help in advance.

Why would a j-pole transmit through your steel mesh walls when your
current antenna won't? Are you planning to stick the j-pole out the
window?

Maybe I'm misinterpreting your words above, but it sounds like you
want to use the j-pole indoors.

You're probably hearing the LCD display multiplexing circuitry. This is
not really RF, it's just the electrostatic effect of being close to the
display.
If you have a tone tracer 'banana' like telco tech use, you can use it
to detect the same effect. I notice that the older monitor CRTs make a
lot of noise when you hold a tone tracer near it, but the newer energy
efficient and most importantly the low emissions monitors don't hardly
put out anything.

I got this translation via Alta Vista... I'm still confused.

At a distance of approx. 50 km air line sandblasts an extremely
hear-worth radiosender (Funradio) in vertical polarization. In the
auto I can receive this more or less quite well, with my home system
am not so easy this to implement. Dzt. I aligned a 7-Element UKW
antenna of the Fa.Wittenberg in horizontal position there. The result
is not real satisfying (Funradio 40 dB, the local senders continue to
come with 78 dB), i.e. in operationoperation operation is there still
an easy noise. The next step would be now 90 degrees a turn of the
antenna, which considering given conditions would be quite complex
however feasible. Jmd. does experience have and can say whether that
could bring somewhat or is not with UKW with the polarization so
delicately?On Sat, 26 Aug 2000 23:01:59 -0700, "Robert BIOWSKI, M.D."

>
> Andrew
> KG4JBM

If it's not 'harmonics' in the true sense i.e. First = 1310, Second = 2620, Third = 3930 etc. it may be due to the strength and proximity of the 1310 signal.
Harmonics are not unheard of though. We used to have significant second harmonic of an 800 kilohertz station; so strong that you could listen to the the program on 1600 kilohertz. Was definitely a harmonic though cos. was the same on all different receivers.
I s'pose your 1310 transmitter could be anywhere? Not necessarily near the radio station offices? Could be on a hill or a high building!
If a strong signal gets into front end of receiver it can mix up with all sorts of other stuff including the signals you 'want' to receive! The unwanted signal could be so strong that it's overloading and like making the front end of the receiver act like a mixer. Or the 1310 may be getting further into the receiver?
As mentioned an attenuator or maybe a trap circuit tuned to reject the 1310 signal in front of the receiver might help?
Doing a little calculating; and assuming your receiver has a first IF of 455 Khz. you may get 'image' reception of what appears to be the 1310 signal at, 400, 1710 (second harmonic), etc. Yours doesn't sound as though it is an image problem.
Another long shot; the 1310 could be mixing (inter modulating) with some other local strong signal outside your receiver. Not common though.
Good Luck.

You are immersed in a sea of RF from ELF to cosmic rays from birth.
We have evolved in it from the beginning. Don't sweat it. Also don't
stare into radar transmitters.

Pagers contain crystal oscillators and down-counters to beat
incoming RF signals against so you can get your messages. Very tiny RF
levels. Chances are the Walkman spills more EM than the pager does. It
has bigger battery capacity and can afford to waste the power.
Different frequencies, but still...

Cellphones (while not transmiting) do the same thing, but most of
the RF is from the countdown circuits driving the clock function.

Do you have a watch with an EL backlight (Indiglo, etc.)? Hit the
backlight button and put the watch next to your Walkman. Kewl.

There's no noticeable difference between any of them. Just
put up the most simple and least expensive - a quarterwave
vertical and be done with it.

Message-ID: <8of125$lb1$1@bob.news.rcn.net>
Source record: 181519

Are we confusing two different items here?

These are not "wrapped" around the guywire end--I think I know what
you are talking about; and Texas Tower carries them.

.
The strand vices are comprised of a stainless steel U loop, machined
aluminum holder, and a bullet shaped device that the guy wire
is run through. The internal mechanism is like a Chinese finger lock;
but the cable can be released with a flat-blade screwdriver by relieving the
spring tension on the cable locking mechanism. They come in
two different styles, one for insulators and one for rod eyes. Virtually
every backguyed telephone pole I have seen uses the Strand Vice device
at the guy rod. Reuse is not an issue, since the guys will have turnbuckles
that can be
undone when needed. They do not appear to be suitable (due to the shape of
stainless steel U loops) for other than insulator or guy rod eye
terminations. I am not
sure they would mate properly with thimbles.

Tom,

Can you give an order-of-magnitude estimate of the radiator size increase
needed to restore the capacatively loaded, folded monopoles efficiency? Can't
be worse than a tubing loop the same area, no?

Cortland
(ka5s@saber.net)

PS: Sent you a .jpg of one of my Bugcatcher experiments mounted.

Roger,
I'm still using many strand vises that I installed on
1/4" EHS guy wire over 25 years ago. I've never
experienced a failure and they still appear to be
in excellent condition. I'd still be using all of them today;
however, I replaced most of my steel guys with 3/8"
fiberglas rod five years ago.

More recently I've been using Big Grips, which are more
readily available in the ham marketplace, and -- like
strand vises -- very easy to install.

Roy:

I, like you, consider email addressed to me as private correspondence, just as I would a private letter or telephone conversation, and will never "publish" such communications.

In fact it is usual in bibliographic work to ask permission of the author of such correspondence before revealing even it's subject matter and then only with an acknowledgement.

Clearly, as we have observed many times on this NG, the NG posters at the "Fractenna" address, do not seem to follow the "norms" of any form of human communications. They apparently have their own rules of behavior in this regard and care little or nothing for the habits and behavior of "conventional" society in this regard. Bohemians perhaps, or...

And so... advice to those who would communicate with Fractenna, should be to do so only with restraint and caution.

There should be one in the ARRL ant handbook. Just crossed dipoles with
a 90 degree phase difference between the two. For what you want to do,
you might also look into a ground screen to have below the turnstile. MK

Tony,
'BugCatchers' work very well, and on the lower HF bands, is
probably
the 'best' mobile antennas. Having used a number of different mobile
antennas, I think the 'BugCatcher' does better than the rest (on 80m).
You don't need all the things you listed to mount a 'BugCatcher'.
A
bottom mast that will get the coil at or near cab height, the coil of
your choice, a cap-hat, and then the whip.
The choices of coil, size of cap-hat, and the length of the whip
are
up to you. The '480' coil, an 18" cap-hat, and about a 5-7 foot whip
will work fine on 80 meters. It may not work too well on 10 meters
though (too long). The impedance matching coil is also very nice to

use. If the quick disconnect is the large brass one, it works okay
too.
A short mast between coil and cap-hat isn't necessary. The quick-
disconnect between coil and whip isn't really necessary, but might be
nice to have. Just be sure to check it often.
I don't use the tap-kit, I use an aligator clip instead. (That's
just
personal preference though. I mark the coil, and can move anywhere
without
worrying about having a tap there.)
If your buying from Henry Allen, ask his advice, he's happy to talk
about it, and won't 'skin' you.
'Doc

This is the greatest advantage - and perhaps the only real advantage.

The improvement in efficiency achieved by using a capacitor instead of an inductor as the matching element is probably unmeasurable using the quality of inductors found in most broadcast ATU's. These inductors typically have a Q in excess of 300. The exception to this might be towers with particularly low base impedances (<10 ohms).

Additionally, in most folded monopoles of reasonable size, you can't find a shorting point that will give you 50 +jXXX, so you are usually stuck using a T or L network anyway.

Harry,
Reg Edwards who you will find on this group has a free DOS prog'
which will help you
calculate the sizes of an helical antenna. I've been playing with it for a
160m mobile antenna, and
it does give some very interesting results!

His web page is on,

Hello,
Some years back I had a QSO with an amateur radio operator, he had a 1/2 wavelength dipole strung along the length of his giant rig!!!

To explain,

Outback in Australia, "road trains" are allowed to run, that is 2 or 3 full sized semi trailers each 42 feet long and all hooked together.

His signal was superb, seeing he was mobile!!!

I used to be mobile on 75/80m for up to 16 hours a day when I was a "truckie", so I was very envious as I had only one trailer in my rig, and had to make do with a helically wound whip...

There IS a civilian version; what you have is called a biconical dipole. It's not much used for communications because civilians don't need the wide bandwidth of a conical antenna. One company (I think it's ARRA) sells a conical dipole that covers 50-1000 MHz with low SWR. It has two cones, each with six or eight elements, each five feet across and five feet long. However, I believe this is mainly used by government agencies in need of a good surveillance antenna. Shorter, less efficient versions of the biconical dipole are used for EMI testing. These show a fairly low SWR from about 70 or 80 MHz through 200 to 300 MHz.

FWIW, your antenna probably works better than the 292 did. And you don't have to take it down when your net changes frequency. Plus you can use a FH rig with it. Anti-jam is nice to have!

No disagreement there.

>I've seen

>does sound logical.

Actually the ground lkoss resistance is almost identical on 160 meters
or 80 meters, because the counterpoise is so small and bulky there
isn't any "room" for major improvements in current distribution.

The vehicle doesn't radiate much on those low frequencies.

>area of asphalt or concrete roadway. Also, avoiding vertical parts of the
>car does reduce cancellation of radiation by nearby opposing currents.

That is part of the answer. The other part is you don't have the high
voltage area of the antenna next to the sheet metal, where the
capcitance effectively "short circuits" the antenna and prevents the
upper part from contributing as much to radiation.

The Hustler is OK, but it isn't high efficiency by any means. Bug
catcher or aixdux/miniductor type coils have much less loss.

Bandwidth has little to do with efficiency in a mobile antenna.
Bandwidth is mostly a function of reactance needed to resonant the
antenna, rather than resistive losses. It's common folklore than
narrow banded antennas are efficient, but it is generally untrue.

That surprises me. If an antenna is mounted at the center of the roof of a five-foot high vehicle, I'd expect the vehicle to be essentially a five-foot high radiator. (Horizontal components would cancel out due to symmetry.) Because of the capacitance to ground, it should have nearly constant current on it, which would make it radiate as much as a five foot high top loaded whip. That would have it producing a field which is only 3 dB down from the field from a 10 foot high top loaded whip. Or is something wrong with my assumptions?

YOu might try making an antenna and seeing how that works. Doesn't usually take much for the repeaters from your house. Just use a good grade of coax to feed it with. Atleast rg-8 or maybe the 9913 type.

If you wan tto buy one, there have been some on e-bay that resemble the Diamond or Comet antennas for less. The Diamond or Comet antennas seem to work fine. I would probably stay with the cheaper modles and not the higher gain ones as you will not really see that much. The gain numbers on antennas that you see seem to be just made up and not a real world number. I think they are refferenced to a handy talkey antenna as it would take one about 20 feet long to get 6 db over a dipole.
Stay away from the Cushcraft Ringo typw of antennas.

This is a clear cut case of harassment and libel. I am particularly disturbed by this effort to embarrass me publicly, while, via e-mail and after this post, Wayne gives the contradictory effort to interact with me and, indeed, state positive statements. In other words, the NG creates and environment where people say exactly the opposite of what their actions pose.

I am posting an UNSOLICITED e-mail exchange, done without any effort to state the e-mail was confidential or private, from Wayne at the wggvideo@attglobal.net:

<<Chip, went throught your site last night and it's really quite inpressive. It's
quite way above my head, in fact I have read some of the disscussions on the anntenna NG (general questions form others, not the sitr your antennas seem to bring up) and I'ts really amazing to hear the depth engeneering some of those guys are into...."

I replied:

"Wayne. I'm sorry but I don't feel comfortable with friendly e-mail banter, given your hostile and denigrating public comments on the NG.

Realize that the NG is not a bulletin board, and is read and accessible globally and in an archived fashion. Such comments are painful to me personally and have measurable negative impact on my efforts--both scientific and in providing for my family.

Kindly do not e-mail any more.

I do respond, as do others, on the fractal antenna reflector to fractal antenna questions.

Cordially,

Chip"

I will not be a public focus for harassment and abuse.

I will continue to encourage hams to understand and pursue fractal antennas, and will answer them in an objective and cordial public forum: the fractal antenna reflector--

fractalantenna-subscribe@egroups.com

In any case, maintaining a hostile environment so that people do NOT want to say positive things on this NG--and have to do it as e-mail-- is surely the death of this community.

1161. Antenna Wire Material

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-28 00:00:00 UTC
From: Jesper Wolf Jespersen <jwj@ehuset.com>
Message-ID: <s1sq5.117$HA2.2548@news.get2net.dk>
Source record: 181631

Hello there.

I went and built me a new antenna this weekend.

Its not exactly a fancy antenna, a two legged dipole for 40, 20 and 15 metres.

The Wire I used was 1.3 mm steel wire with transparant plastic coating, this was selected for strength since the antenna carries it self, the balun and feedline and thus needs to be pretty taught.

The dipoles are terminated in antenna eggs (porcelain insulators) and tied to 5 mm flagline (synthetic).

The end points are two trees at the back of the garden, in aproximately 4 metres height and two antenna posts on the roof of our house in about 8 metres height. All antenna endpoints are at least 2 metres from any "ground" potential and they are hanging free.

The two legs ended up being 4.755 m for the 20 metres band and 9.84 m for the 40 metres band, they are space aprox 45 degrees horisontally. (Looks like a giant spider had started a web over the garden :-)

The VSWR on 40 is below 1.6 at the resonance point 7.075 MHz, on 20 m the VSWR is below 1.8 at the resonance point of 14.200 MHz.

But the antenna does not have a resonanse on 15 m and the VSWR here is above 2 all the way, falling a bit towards the higher frequencies.

I dont realy understand this, I would have expected a clear ressonance at 21.230.
Likewise I would have expected the VSWR's to be lower. (1.2-1.5)

Previously I had two dipoles up using copper cable, 1.5 square mm strength, for the 40 and 10 metres bands. Placed at exactly the same position as the two I have now.
The 40 metres dipole using copper cable was aproximately 20 cm longer with the same ressonance frequency as the steel wire, and I had a nice VSWR below 1.6 on 15 metres.

The reason I changed the setup was that the antenna didnt work to well in wet conditions, the synthetic line was simply a signal drain when wet and since the antennawire was just piggybacked on the flagline there was no way to isolate them.

I changed the 10 Metres dipole to a 20 Metres dipole simply because I had more traffic there.

Now I am a bit baffled because I cannot get the calculations to match this antenna.

Normally the length of an antenna is given by the formula :
L = 0.95*(300 / F0)/4

L : quarter wavelength
0.95 : light speed reduction in antenna material
300 : Speed of light (million kilometres pr second)
F0 : Centre Frequency in MHz

The lengths of the two dipole legs would have been 10.07 m and 5.02 m if this equation was exact.
It seems the speed reduction factor is larger for steel wire, but the two legs indicate different reduction factors:
0.93 at 7 MHz and 0.90 at 14 MHz.

This does not seem resonable, the steel wire is not as good a conductor as copper but I would expect the speed reduction factor to be constant.

Have I been dumb in selecting this antenna material ?

I have tried to check for errors, have checked that the legs are symetric and even cut a few branches of a plumb tree that came close to the antenna. But I have no explanation for the phenomenon.

The antenna Works, I have had DX contacts on both 40m and 20m, but I cannot compare to my old setup. The conditions on 20 have been poor over the weekend so I cannot say if the antenna is worse than before.

Does any of you have helpfull comments ?

I think it is fun experimenting with antennas, but I like to see progress or at least a good explanation to why I had a setback.

Greetings from Denmark

Jesper Wolf Jespersen

Source record: 181632

Um, Chip, Methinks your skin be too thin.

He did say "seems", which, to most people, indicates a personal opinion or viewpoint is being expressed. He didn't say "is", which would be a statement of fact. As I see it, his comment was not directed at you personally, nor does it seem to have been phrased to denigrate, degrade, slander, libel, or otherwise harm you, your business, or your family's supper.

Please note: THE FOLLOWING IS MY PERSONAL VIEW ON THIS SUBJECT, and is not a statement of fact. It seems to me, reading your responses to other posts, most oft taken out of context, that you have been baiting the readers of this news group in order to foster a "poor me" feeling amongst the netizens herein, thereby passively marketing your antenna(e) passively to those susceptible to the "sympathy purchase".

This, I feel, is why some have outwardly criticized your posts, and have gone as far as to assume everything posted by "somename"@aol.com, who has never appeared anywhere in any news group (nor anywhere since then) has been an "alternate personality" of yours, to foster some support for your particular ideas and potential products.

Then again, their outward objections to this perceived tactic has enabled you, in my view, to continue garnering sympathy ("poor me, buy my antennae") by posting messages alluding to lawsuits, etc, which prompts more outward objections, which prompts you to post some more about lawsuits, ad infinitum. It seems (there's that word again!) to be a never ending cycle, which resembles poison ivy (there's that metaphor again).

If we were ever given technical specifications about your antennae, where they would be best put to use, where their efficiency gain is seen, conditions under which another antenna would be a better choice, etc, I have never seen it. I have seen posts about web sites which provide vague data (at best), web sites showing patent applications which read like stereo instructions that were originally written in Swahili, translated to German, then Japanese, then finally English, and no other real data upon which I could base an opinion one way or the other on any fractal antenna design.

All I have been presented with is threads upon threads upon threads of people asking for information, you claiming it's an affront to your potential business prospects, and you threatening lawsuits, etc, against the netizens of this particular news group.

Would it be possible to end this chain of perceived abuse, statement
of opinion, threats, insults, and the like, and get some real data on
this subject so that we may make an intelligent, informed decision as
to the merits of such a technology, and where it would best be used?

Or are we to continue upon the present path, in which no one gets any
answers, and nothing is accomplished?

Just the two cents of a CB'er who hopes one day to become a HAM.

-SSB

1163. wanted schematic turnstile antenna for 137 MHz

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-28 00:00:00 UTC
From: Antoon Milatz <antoon.milatz@tek.com>
Message-ID: <39AA5456.6C8A1DBE@tek.com>
Source record: 181633

Looking for schematic/mechanical layout etc for turnstile antenne for
receiving 137 MHz wx satellites.
Any hints/links/info appreciated.

Antoon (pa3bwe@amsat.org)

1167. Re: Is there an effective 75 meter mobile antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-28 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8odn9pbjr1@uranium.btinternet.com>
Source record: 181637

Below 10 MHz, an HF antenna mounted in the center of the roof of a small vehicle behaves as a short, 1/2-wave-resonant, roughly middle-loaded vertical, near the ground.

The lower portion has a large conductor diameter with the bottom end connected to mother earth via a calculable air-spaced capacitance. The ground, in effect, is a 'bottom' capacitance hat. The series loss resistance of the hat capacitance is also calculable when the soil resistivity is known. (But this need not take the fun out of shoot-outs.)

The large 'bottom' hat causes the current in the lower portion to be more uniformly distributed along its length rather than having a triangular distribution as in the top portion. So the resulting radiation resistance of the whole system may be roughly twice that assumed in ARRL bibles where only the length of the portion of the antenna above the roof is considered.

When the whip is mounted on the rear bumper the effective overall antenna length and radiation resistance are much the same as a shorter roof-mounted whip having the same overall height restriction. As pointed out elsewhere, this will be less efficient than roof mounting because the direct capacitance of whip-to-vehicle-body increases circulating current through the loading coil without contributing much to radiation. As ever, parasitic capacitance increases coil loss and decreases effective Q.

On the other hand, coil loss does not increase all THAT much because a smaller loading inductance is needed for the longer whip and coil loss resistance decreases in the same proportion. Taking economics into account, there's no need to depress the resale value of your Rolls by cutting a hole in the roof. Whatever would we do without our pocket calculators?

Deary me ! Life gets SOOoooo complicated in this 21st-century hi-tech age !

I think we've been through this before, and someone even modeled a car
and found radiation from the car body wasn't a factor no matter where
the antenna was mounted.

The thing that spoils that idea is the path is very wide, and
capacitance is distributed all over the vehicle. Current spreads out
in all directions from the mounting point, instead of flowing in a
single line from end to end. The vehicle looks nothing like the skinny
conductor with capacitance at the end.

I can't recall who did the model, maybe it was Cecil. In any event
radiation from the vehicle is greatly over rated. It's a bit like the
idea the DDRR radiates from the ring, instead of the vertical portion.

Roy, thanks for your concise summary.

Like yourself, when I reply to someone directly, personally, instead of in public view via a newsgroup, I do so because I wish the e-mail itself to be confidencial.

It is extremely rare for me to respond by e-mail. A question asked in public deserves a similar reply if only for the benefit or entertainment of the bystanders. And let's face it - as I'm doing here - like most others - I obtain some satisfaction from the opportunity to talk about myself or my experiences.

On the other hand, any information via private e-mail is obviously available for the recipient to make use of. Its credence is a matter of the recipient's judgement. It goes without saying, the consequences of any following action taken by the recipient are solely his/her responsibility. I wish to receive neither credit nor blame from someone publishing what is obviously a confidential matter.

On yet another hand - when anyone makes a living out of providing information (a professional adviser), should a dispute arise any originally private correspondence may eventually become a matter of public knowledge in the law-courts. But where out-of-control newsgroups, which are international affairs, fit into the Law is merely a matter of conjecture, rent-a-riot, economic sanctions and cruise missiles.

Source record: 181640

Scott Mann wrote:
"When lengthening the antenna the broadcast frequency drops, how does this work?"

Electrical generators, including radio transmitters, have two output terminals. One exudes current while the other accepts an equal amount of replacement current. In the AM broadcast bands, the usual connections are to an aerial and ground.

The circuit Scott posted includes an aerial connection (T1). If there were a T2, it would likely be connected to the negative battery terminal.

Actual grounding is accomplished through stray capacitance between the transmitter and ground. The antenna has capacitance to ground.
Increasing the length of the antenna increases the antenna`s capacitance to ground.
This capacitance shunts the tuned circuit which determines the frequency of oscillations. More capacitance across the tuned circuit means a lower frequency of oscillation.

Best regards, Richard Harrison, KB5WZI

I am talking about a CB antenna, but it's one I built a couple of
weeks ago. I was surprised at how more more than 1/4 waves' worth of wire
was necessary to make a 6 foot fiberglass antenna resonate. My thought is
that because the coils have to be made small and relatively close together
on this 3/8" diameter rod, perhaps large diameter free-standing base loops
as feed from the coax to the start of the small windings would increase
the antennas electrical length without increasing the inductance as much
(and not require 5/8 waves' worth of wire). I've seem some of these
around, although I'm not sure if they are for CB or 10-meter. I agree
though that for the antennas I've seen sold for CB's, they are mostly made
to be convenient and look stylish, not work well.

Although it's been awhile since I took my last EM waves class, I
recall something about the permeability of ferrous material screwing with
the characteristics of an antenna. It will most certainly add more self
inductance to the wire itself. If you are getting a good match perhaps
it's because it's actually running 3/4 or 5/4 wave match. I'm not sure.

-Cory

Jesper Wolf Jespersen <jwj@ehuset.com> wrote:
: Hello there.

: I went and built me a new antenna this weekend.

: Its not exactly a fancy antenna, a two legged dipole for 40, 20 and 15
: metres.

: The Wire I used was 1.3 mm steel wire with transparant plastic coating, this
: was selected for strength since the antenna carries it self, the balun and
: feedline and thus needs to be pretty taught.

: The dipoles are terminated in antenna eggs (porcelain insulators) and tied
: to 5 mm flagline (synthetic).

: The end points are two trees at the back of the garden, in aproximately 4
: metres height and two antenna posts on the roof of our house in about 8
: metres height. All antenna endpoints are at least 2 metres from any "ground"
: potential and they are hanging free.

: The two legs ended up being 4.755 m for the 20 metres band and 9.84 m for
: the 40 metres band, they are space aprox 45 degrees horisontally. (Looks
: like a giant spider had started a web over the garden :-)

: The VSWR on 40 is below 1.6 at the resonance point 7.075 MHz, on 20 m the
: VSWR is below 1.8 at the resonance point of 14.200 MHz.

: But the antenna does not have a resonanse on 15 m and the VSWR here is above
: 2 all the way, falling a bit towards the higher frequencies.

: I dont realy understand this, I would have expected a clear ressonance at
: 21.230.
: Likewise I would have expected the VSWR's to be lower. (1.2-1.5)

: Previously I had two dipoles up using copper cable, 1.5 square mm strength,
: for the 40 and 10 metres bands. Placed at exactly the same position as the
: two I have now.
: The 40 metres dipole using copper cable was aproximately 20 cm longer with
: the same ressonance frequency as the steel wire, and I had a nice VSWR below
: 1.6 on 15 metres.

: The reason I changed the setup was that the antenna didnt work to well in
: wet conditions, the synthetic line was simply a signal drain when wet and
: since the antennawire was just piggybacked on the flagline there was no way
: to isolate them.

: I changed the 10 Metres dipole to a 20 Metres dipole simply because I had
: more traffic there.

: Now I am a bit baffled because I cannot get the calculations to match this
: antenna.

: Normally the length of an antenna is given by the formula :
: L = 0.95*(300 / F0)/4

: L : quarter wavelength
: 0.95 : light speed reduction in antenna material
: 300 : Speed of light (million kilometres pr second)
: F0 : Centre Frequency in MHz

: The lengths of the two dipole legs would have been 10.07 m and 5.02 m if
: this equation was exact.
: It seems the speed reduction factor is larger for steel wire, but the two
: legs indicate different reduction factors:
: 0.93 at 7 MHz and 0.90 at 14 MHz.

: This does not seem resonable, the steel wire is not as good a conductor as
: copper but I would expect the speed reduction factor to be constant.

: Have I been dumb in selecting this antenna material ?

: I have tried to check for errors, have checked that the legs are symetric
: and even cut a few branches of a plumb tree that came close to the antenna.
: But I have no explanation for the phenomenon.

: The antenna Works, I have had DX contacts on both 40m and 20m, but I cannot
: compare to my old setup. The conditions on 20 have been poor over the
: weekend so I cannot say if the antenna is worse than before.

: Does any of you have helpfull comments ?

: I think it is fun experimenting with antennas, but I like to see progress or
: at least a good explanation to why I had a setback.

: Greetings from Denmark

: Jesper Wolf Jespersen

Well, here's my main problem. I live just south of Birmingham, Alabama.
Between me and Birmingham is a mountain (Double Oak Mtn)! I can hear all the
repeaters just fine, but my five watt hand held just can't reach them, even
using a tree mounted antenna. That's why I got the new radio, hoping a
little more umph will let me get over the mountain to the repeaters.

I think I'll start off using the antenna I have on hand and see if it will
get out. (It's a MFJ portable J-Pole on the end of 50 foot of RG8, stuck up
in a tree). If so, I'll just stick with it.

By the way, does anyone know where I can look up the radiation safety
tables? I want to be able to use the 45 watt radio in my car. I have a mag
mount antenna which is on the truck right now. However, I want to be sure
not to harm my two young daughters when they ride in the back seat. I wanted
to see if I needed to move the antenna up to the roof, or is it OK on the
trunk.

Thanks again to everyone,

Robert KG4FGN

The physical length of a wire inside an antenna, when it is not
spatially in a straight line, has little to do with electrical length.

It's a common misunderstanding that a coil loadsing an antenna (a
helical antenna would fit this description, except the inductance and
capacitance is distributed) "makes up for missing length" .

All the "extra wire" does is provide inductive reactance to cancel
capacitive reactance.

CB manufacturers try to jam as much wire in a given area as they can,
and still have resonance, because they can sell the antenna to people
who think more wire in a small space somehow is better. This pretty
much always increases losses over an optimum form factor.

What has happened to Cecil? It is not like him to miss all the "fun" that goes on here! Especially when mobile antennas and shootouts are mentioned.

Renee,
Yes you can do it quite easily; the biggest problem may be lenght of
the power run for the motor.
If you contact HS that have a very good multiband counterpoise
description that you can build using 300-twin lead this information
normally was sent with the antenna but I am quite sure that if you
contact them they will send you a copy.

(HINT HINT HINT may be they will put it on the web page)

I have installed (3) on my garage roof for emergency work and even
went to the point of putting some in on my beach cabana this way I can
bring my 706, some hefty gel cells and the antenna and use it at the
Hamptons.
Yes I do get some strange questions about it but I just tell them that
it is a "cell phone booster".

BTW if you want you can paint the antenna to match.
Some one that is living in a NO NO community painted his to match the
brickwork of his chimney and from the ground it is Invisible, he
braided the counterpoises into the architectural roof shingles.

Enjoy...

The real problem with permeability is that it reduces the skin depth, which in turn increases the RF resistance. If a wire has a relative permeability of, say, 100, its RF resistance is ten times greater than it would be if the relative permeability were one. Steel has high resistivity to begin with, so the combination results in a very lossy antenna. Loss will increase the antenna's bandwidth, with the extreme case being essentially a dummy load. Steel wire isn't a good choice if you want to radiate the maximum amount of signal.

Comment re above.

Lived in an aluminium shell trailer many years ago. Couldn't receive a thing inside, most frequencies, (so I probably could not have transmitted out either!). Even had to put our receiving TV receiving antenna outside on a four foot fence; it worked quite well even when buried in snow!

Also our first house was completely lined with aluminium foil, in addition to fibreglass insulation. That also weakened the reception of all radio signals, although we were on a hill which possibly helped?

Point I'm making is that any metallic 'shell' will tend to contain radio waves within it or prevent (weaken) radio waves coming in.

I gather that almost 'anything' outside, even a very fine gauge wire dangled out of a window with an inconspicuous weight on the end is better than anything within the metallic shell of a steel framed or meshed building? For example the local Radio Shack stores are almost always in steel framed buildings. They will tell you "No good trying to test anything in here! a) Too weak a signal and b) too much electrical interefrence. Electrical pollution shouldn't be allowed btw.

Quite often there have been postings about inconspicuous or 'secret' antenna on these news groups.

This is a bit off the topic but one famous amateur told me that he managed to 'load up' (by experimenting with the matching to his mobile transmitter) the roof section of his all metal body saloon car! And actually made a QSO with it! So the message might be that if you temporarily put your metal ironing board out on an apartment balcony and match it up, somehow, to your transmitter it MIGHT work.

An idea.

Jesper,
I don't think the problem is the steel wire that you made the
antenna from, so much as the change in bands covered. The old antenna
used a 40 meter and 10 meter combination. The new antenna uses a
40 meter and 20 meter combination. I think that's why 15 meters

doesn't work so well on the new antenna.
What you make the antenna out of, copper wire or steel wire, will have some affect on the efficiency and length of the antenna. As long as the material used is within reason, you should get satisfactory results. (Copper, steel, aluminum... reasonable. Nichrome, or other 'resistive' types... unreasonable. I'd include silver and gold wire in the unreasonable group too!)
Try changing the 20 meter part back to 10 meters, that may 'cure' the 'set back'.

rsm wrote:
>
> Does anything really work very well?

The 'quick and dirty' answer is, no. But that depends on
your definition of 'well'. If you start of realizing that
a 10% efficiency mobile antenna is probably the 'best' you'll
ever get, then you will find that there are a few 'good'
80 meter mobile antennas.
The 'key' to mobile antennas is "big and ugly". The lower
the frequency, the bigger and uglier the antenna. For the
'best' 80 meter mobile antenna, get the biggest and ugliest
you can find. (Not a very scientific solution, but you'll
find that it's true.)
'Doc
PS - Another helpful hint for mobile operation;

Hi Tom

I note that in Jack Belrose article in Volume 4 of the ARRL Antenna
Compendium on HF mobile antennas. He shows calculated azimuth antenna
patterns varying about 4 dB, depending upon the antenna's location on
his GMC Jimmy truck.

BB,

I read all the other posts but no one actually gave you a web
site to look at. Here is the address of a web site that features
a twin-lead J-Pole for 2M/440MHz. It also has one that fits
in a piece of 3/4" PVC.

http://www.thedragonmaster.com/j-pole.html

Good Luck with it.

I'm more than happy to help:-)

Since 1995 I have published about a dozen articles in ham magazines detailing such specifics. Thus, may I suggest you look in the ham literature, and the NG archives for suggested articles, OR, pose your question on the fractal antenna reflector?

Also, on the ham page of

http://www.fractenna.com

you will find two of many examples of fractal antennas which are SUPERIOR TO OTHERS IN PERFORMANCE for the needs they address. Not equal, not ok, but SUPERIOR.

You will also note that, to help demonstrate this, I have posed a $1000 CHALLENGE. So far, none of the entries have come close:-) Check the back posts for your enlightenment on the objectively stated rules:-)

It's a pleasure to see your interest in fractal antennas and I actively urge you to explore further and ask interesting questions! As always, time permitting, I will be happy to help through the reasonable and responsible means I have outlined.

You will also note that not only have I been forthcoming with said info in the last 5 years, but continue to take time from a bust schedule to answer the deserving:-) Just come to the fractal antenna reflector:

fractalantenna-subscribe@egroups.com

I regret that I cannot answer more specific questions on fractal antennas on this NG: the fractal antenna reflector has been found to be the best way to help others and provide a meaningful, fun, and archived record.

Very Best to you!

Has anybody had experiences with the Spi-Ro brand trap dipoles? Want to put up a multiband resonant dipole. The W9INN's seem to perform very well (heard much good about them) and was just curious about the Spi-Ro's. TNX in advance.

The 300-Ohm twin-lead 2-meter J-Pole works great on 2-meters, but those who claim it to be a dual-band antenna are wrong. Yes, the SWR is low, but the performance stinks, to put it mildly.

Source record: 181662

Chip:

The website is nothing more than the same data which has been bandied about for who knows how long. Not to mention there are no real test data concerning I'd asked some specific questions about where, on the web, I might find performance data and/or comparisons between the fractenna and a "conventional" antenna.

Specifically, I'm seeking comparison between:
A. a dipole in free space vs fractenna in free space
B. a dipole in real space vs fractenna in real space. real space being defined as in a tree, on a tower, along the side of the building.
C. a dipole below ground, not buried, vs fractenna below ground, not buried. For example, in a basement.

Dipoles should all be vertical.

In all cases, I would like to see the following test criteria met.

1. Both antennae should be tested in the same space, or as close to the same space as is possible.
2. The same transmitter is used for all tests.
3. The power of the transmitter is not varied.
4. The transmitted frequency is not varied more than 10 cycles throughput the test.
5. The transmission will be an unmodulated AM carrier at 2 watts RMS.
6. The same field strength meter will be used for all tests.
7. The location of the field strength meter will not me changed between tests of the two different antennae in the same location.
8. The field strength meter will be no less than 4 wavelengths from the antenna, and no more than 20 wavelengths from the antenna. Further away is preferable.
9. The antennae should be "tuned" for best SWR possible.
10. The tests should be conducted both by you, Chip, as you claim the antenna's superiority, and by a volunteer from this newsgroup. I cannot perform the tests myself, as I lack the required equipment, and I am unable to hang external antennae at my apartment.

Most of the azimuth plots are at 30 to 33ï¿½ elevation. His graphs show
total, horizontal and vertical. Total and vertical are very close with
a very small horizontal gain in a more or less dipole type pattern.

Danny

1194. Texas Bug Catchers --- Any Recommendations

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-28 00:00:00 UTC
From: Tony Hackenberg <mehawh@earthlink.net>
Message-ID: <n1Cq5.3546$p5.107977@newsread03.prod.itd.earthlink.net>
Source record: 181664

I'm thinking about purchasing a "Texas BugCatcher" antenna from GLA Systems for mobile work. Yet, I have not heard much discussion about them in this newsgroup. Any recommendations or advice on BugCatchers?

Since you can mix & match the basic components of a BugCatcher antenna, GLA's order form and web page (http://www.texasbugcatcher.com) are complicated. Adding to the complexity, many of the components come in differing sizes to better tailor them to your needs. I'm planning on using the BugCatcher on my Ford F-250 (1989) truck. I want to work 80-10 meters mobile. I've scoped out the following tentative list of components for the BugCatcher antenna:

Model - GLA Systems' Texas BugCatcher Antenna (non-remote tune; not motorized)
Mount - "Fold-over Trailer Hitch Mount" ($95)
Quick-Disconnects - QOL (Long Base Screw-Off) ($32)
Matching Coil - HD80 ($35)
Mast - 5' ($38)
Quick-Disconnects - QOM (Short Base Screw Off) ($30)
Loading Coil - #480 Coil ($139)
Extender Mast - Short Mast before Hat ($?)
Capacity Hat - 6 inch diameter ($20)
Quick-Disconnects - QOS (Small Screw-Off for Whip) ($20)
Whip - 72" (6' - 3/16" x 102") ($18)
Extra Coil Tap Kit - Spare coil taps etc ($12)

1195. Anyone using Strand Vise for tower guys?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-28 00:00:00 UTC
From: Peter Bertini <commquart@erols.com>
Message-ID: <8oerq4$f7n$1@bob.news.rcn.net>
Source record: 181665

I have a source for Strand Vice and telephone style guy rods with mushroom caps.

Has anyone used or have heard any pros or cons regarding the use of Strand Vices in
lieu of cable clamps to terminate the ends of the guy wires? It seem strange I don't see
these products being used on towers--just utility poles. Any reason for this? I am
considering using the Strand Vices on my new Rohn 25G foldover tower next year.

Peter:

There is good reason that you don't see them used
on towers to a
extent. That being that they are good for one
wrap-up when you
undo them the "grit" that holds the galvanized
stranded guy wire for
utility pole use is gone; get another guy wrap.
Now they could be used
quite successfully on guys where you put strain
insulators, but down
at the bottom where you might be re-tensioning the
cable, go for
thimbles and cable clamps. Al Piper; Central
Valley Electric Co-op
Inc. Just a chicken bander, but with two towers on
his place.

Tom:

There is one more very important difference: Q the
open
air large coil type antenna is VERY broad banded.
While
the 'ole 1/4 whip is acceptable, if you strictly
run the normal
40 channel spectrum and do no free-banding. Two: I
personally have ran a swr bridge in-place for
years and
after resonatanting a 108" whip and getting it
flat at the
particular freq. range that you use (I run SSB
exclusively,
so I want it flat at 27.365>), set the swr bridge
standing
still and then go mobile and watch the swr go up
as the
antenna leans back in the wind. I've used the 'ole
fishing
line and plastic tab with gutter clip method of
guying the
whip, but who wants to go to that trouble and make
the
car look funky. I currently run a Hustler MO-1
with the
RMS-11 resonator on my wife's car. I run a Workman
Terminator twin external coil on my P.O. They are
both
very broad banded to the tune of 20+ above and
below
the band edges with an 1.3-1 swr. But I'm just a
dumb
chicken bander with 26 years experience and 3
copies
of the ARRL antenna handbook '56 - '74 & '99, but
I
probably don't know enough to be called a newbie.

Could you elaborate in this? My PCR-1000 has several *modes* but darned few filters. In fact, it is broad as a barn door on SSB and CW - too much so to be an effective receiver for other than casual monitoring. Just no room in that little box for any real filters and the DSP add-on doesn't offer much more.

I got one of the early ones, so maybe Icom has improved the design.

Hi,

You can build a 2m antenna called the half square for under $ 5.00 while
you are waiting for the radio to arrive !

http://www.cebik.com/

click on technicals and then page down to half square.

It is a very good antenna and if you want to you can build a
2m beam at this web site www.softcom.net/users/kd6dks/quad.html
(or for any frequency.)

good luck and 73

I have to agree with you Fracadolf reposted my email also
apparently the rules of good conduct and gentlemanly behavior
simply don't apply to Nathan the twirp.

His behavior put me to mind of a quote from the old Star Trek.
A Klingon having had just about enough of James Tiberius
Kirk lets go with,"You're a two bit tin plated dictator with
delusions of godhood". If the quote don't fit Chipper don't
wear it so often.

Sorry Chipper the bottom line is that you are a twirp and
apparently were not rased right, sue your parents.

You're forgetting something here. You MIGHT be able to modify it
legally as a licensed amateur under one condition - no one can call
in! Remember, even with the autopatch in a repeater, it may only be
controlled by a licensed amateur, therefore it is for outgoing calls
only! If you only modify the handset, you couldn't talk to an
unlicensed radio; therefore, this is going to be an outgoing unit only
since it will be a licensed amateur radio station.

Got an antenna question that's been rattling around in my (admittedly mostly empty) mind for a while now...

I'm in the Army and spend a lot of time in the field, much of it communicating over various FM radios. The standard Army FM "base station" antenna is the OE 524 (the successor to the 292 to you old timers out there). This antenna has 8 elements, four pointing up in a "crown" pattern angled about 70 degrees from the hoizontal, four pointing down in the same approximate pattern. The four pointing up are, I assume, the driven elements, the four pointing down are the ground plane elements. The Army is obviously in love with this antenna; as far as I can tell it's been in use since the '60's. However, I have never seen this antenna duplicated in a civilian form. That would tell me that it's not as good a performer as it's military popularity would seem to indicate.

Can anyone tell me what the theoretical performance of this antenna arrangement is and why it's so popular with the military and not the civilian market?

Hi Robert,

The R.S. discone's wideband characteristics end around 120 MHz. The 30-50 coverage is achieved as a groundplane and is very narrow band- this antenna will not give you frequency coverage at HF- which is what I think you are referring to w/ your upcoming general class license.

Yagis work fine, but unless you are out on the great plains the usually are
not necessary to work repeaters.

Another thought is that if you are going to be working repeaters and there
are lots of them in your area you don't want a "high" antenna.
I moved mine down so the base is abut level with the bottom of the eves and
the peak of the roof is at least half way up the length of the antenna as I
hear Battle Creek all the time, but they are a tad close.

When working repeaters performance is "usually" no big thing. Your maximum
distance for normal propagation is about 13% beyond the distance to the
horizon. That does not take a great deal of power, or gain.

However, when I finally
> upgrade to general I'll already have an antenna up.
>
> Most of the repeaters are north and west of my house, however there are a

>

Depends on the distance to the repeaters and the distance to the next closest on the same frequencies. If one is 20 miles in one direction and the other is 105 (if they stick to the 125 mile rule) you will be keying both with anything other than a relatively low antenna and power. Here the Yagi might help though as it *might* reduce the signal off the back enough that you wouldn't key the repeater in that direction.

I say that power and gain are not important as I can easily work 150 plus miles from the airplane using 5 watts or less and a rubber duck antenna. That is from well less than 10,000 feet.

1212. Doublets and Baluns

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-29 00:00:00 UTC
From: bejones@hursley.ibm.com
Message-ID: <39ab888a.8139514@testnews.hursley.ibm.com>
Source record: 181542

For IARU region 1 field day this weekend I'd like to use a 160' doublet fed by 450ohm balanced line. I've used this before with reasonable success. Sadly I doubt we'll get it much over 30' high unless the trees have grown and our catapultist is on particularly good form.

The problem is my local club members are not contesters and many of them not particularly experienced operators. Many of them will be unfamiliar with the equipment and some may not even have used a manual ATU before. To simplify matters I intend to use the ladder line all the way except for the last 8or9' into the caravan. Here I'll stick a 4-1 balun (I got a RadioWorks 4-1 current balun) and feed 50 ohm coax - not only does this mean the TS850SAT built in ATU might be able to match the antenna but also keeps the balanced line at a little distance from the aluminium bodied caravan.

Questions:

Is the TS850 built in ATU likely to provide a reasonable match on all bands in this configuration?

Any better ideas for multiband 80-10m operation?

Sadly my tiny home garden doesn't lend itself too well to antenna experimentation so I can't test this out empirically.

1213. Re: Is there an effective 75 meter mobile antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-29 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39AB979B.180AF024@eznec.com>
Source record: 181543

I did a quick EZNEC modeling experiment. I made an 8-sided cylinder (that is, like a cylinder but with octagonal ends and 8 flat sides). The cylinder was 5 feet in diameter and 5 feet high. Its bottom was 1 foot above the ground. The cylinder was modeled as a skeleton, with 8 radial wires and 8 periphery wires making the top and bottom faces, then 8 vertical wires connecting the top and bottom faces. At the center of the top of the cylinder I put a five foot vertical wire, fed at its base. So what I had was a dipole, with the upper half normal sized (#10), and the lower half being 5 feet in diameter. All wires in the model were #10, frequency was 3.5 MHz, and "Real, High-Accuracy" ground of average characteristics was used.

The current on the cylinder began at the feedpoint at the center of the top face, then went to the edge of the top, downward along the vertical wires to the bottom face. Some, but not much, current, flowed from the edge of the bottom face to its center.

The current on the whip was as expected -- it tapered linearly from the bottom to the top. On the sides of the cylinder (that is, the vertical wires), I expected a fairly uniform current due to the "bottom loading" effect of the bottom face. But the current did decrease from the top of the cylinder to the bottom along the vertical wires. The decrease was approximately linear. But it was only about a 2:1 ratio. That is, the current on the vertical wires was about twice as large at the top of the cylinder as at the bottom, and there's quite a bit of current flowing onto the periphery wires at the bottom cylinder face. I took the approximate average current in one of the vertical cylinder wires and multiplied by eight to get the total current along the vertical wires. The result was 0.4 amps, not too far off from the 0.5 amps average for the whip (which was fed with 1 amp at its base).

I replaced the cylinder with five feet of #10 wire. The current on the whip was essentially the same as it was before, so the field from the whip was the same as before. The total field from the antenna was only slightly changed, being 0.45 dB lower than with the cylinder. If the field is about the same as before and the field from the whip is the same as before, then the field from the cylinder must be about the same as the field from the 5 foot wire I substituted for it.

The cylinder is admittedly a very crude and idealized model for a car. But it does illustrate what I had proposed earlier -- that the car can indeed be a significant radiator -- at least if the whip is placed at the center of its top. Top loading of the whip will certainly alter the current distribution on the whip, and perhaps also on the car, so the ratio of radiation from each will be affected by the loading. Also,

placement of the whip on one end of the car should result in some non-cancelling horizontal currents, which would be expected to incur quite a bit of loss due to coupling with the ground, and would radiate mostly straight up with what field is left. It's admittedly a complex issue, but I think some modeling of simplified cases can give some insight into what's happening.

Hello all.

Thank you for the nice replies to my query.

The sugestions have varied, most agree that steel wire was not such a great choise after all.

But only one adresses my problem, that I cannot tune up on 15 metres.

He sugests that the combination of dipoles for the 40 and 20 metres band may have a problem on 15 metres.

But I think I have seen excactly this setup sugested in this conference and in amateur magazines.

The 20 m dipole is about 1/3 wavelength on 15 metres and shouldn't be a problem if it stays well away from the 40 m dipole which is at 3/4 wavelengths on 15 metres.

I will try and shorten the 20 m dipole to a 10 m dipole and maybe even remove it to make sure what the problem is, one never knows when reality choses to defy theori :-)

Greetings from Denmark

I hope no one jumps to the conclusion that "significant radiator"
means the car adds a significant high-angle signal to the radiation.
That is the point that most people seem to misunderstand. I think that
misunderstanding is rooted in claims made by Don Johnson and others
that "significant high angle radiation" occurs from the vehicle.

Of couse "significant" is a subjective term.

I wonder how the car would compare to a flat sheet about the same area
as a slice of the car that would involve the upper areas of
sheetmetal.

>ratio of radiation from each will be affected by the loading. Also,
>placement of the whip on one end of the car should result in some
>non-cancelling horizontal currents, which would be expected to incur
>quite a bit of loss due to coupling with the ground, and would radiate
>mostly straight up with what field is left.

That's a reasonable way to say it, as long as people pay attention to
words like "some" , "quite a bit of loss" and "what field is left".

Several months back on this newsgroup someone claimed the shootouts
in California were "mostly measuring radiation from the vehicles, and
not the antennas".

Most cars are around 5 feet tall, and 12 feet long, and six feet wide.
They have considerably more horizontal area than height. An exception
would be something like a van. It seems reasonable the longer lengths
of antenna with current flowing straight up would be much better
radiators than the vehicle.

I've e-mailed Cecil because I think he was the one with the model of
his vehicle.

David,

Whatever works for you in exercising restraint has a practical and beneficial outcome, where people don't need to fear the ridicule and intimidation of abusive discussions, and instead can engage in objective discourse. So even if your MOTIVATIONS are incorrect, let the RESULT continue.

I have made very positive moves to reach out to those who are crying for my attention and have felt compelled to abuse, to see if a personal touch helps. For example, I offered to meet and take Chuck O'Neal , K1KW, out to lunch at Boxboro the other day, with no response.

I will add that should offendors , such as yourself, behave yourselves, I may be willing to continue answering fractal antenna questions on this NG.

As of now, I only answer such questions on the fractal antenna reflector:

fractalantenna-subscribe@egroups.com

Have nice day!

very 73,

Unfortunately not. The ATU in most tranceivers is not designed to match
"untuned" antennas, only to "flatten" the SWR your tranceiver sees on
antennas
that are already resonant.

> Any better ideas for multiband 80-10m operation?

A G5RV would probably work well, and the ATU in the TS-850
should be able to match it fairly well.

Everyone who has responded to this thread has mentioned the internal RF frequency (IF) in most radio receivers, including pagers and walkmans.

But, is your pager a two-way pager? In that case, it is actually transmitting information.

As also mentioned, most electronic devices emit RF. Ever put an AM radio next to your computer? You're getting a boatload of RF energy from not only your computer, but the monitor as well.

If you don't like being hit with RF energy, you're almost out of luck these days in our modern society.

But if you move to some place without these modern devices, you'll still be hit by cosmic rays from outer space!

Hi Vic--

Fist thing, I guess, is to get a portable radio (a HT with the airband should work pretty well--need an AM detector--and noise is a little easier to localize at VHF). Then start walking the fences--could be one is a lot worse than the others. Causes could be grass or branches touching the wires, poorly made splices, cracked or dirty insulators, gate connections, or anything else that might draw a spark. Some older units may be noisy, too. When the fence is installed and working properly, there should be little or no noise from it. If the fence is really noisy, it may be a sign that it isn't working as well as it should and the farmer may have a vested interest in fixing it.

I called the number in his advert a few years ago and the guy faxed me some info. It looked fishey to me and I faxed some questions back to him. Never got an answer from the Dovetron Steath to questions such as how his antenna performs in relation to a dipole at 30 feet. Needless to say I did NOT get one. If you need stealth, you would likely be better off tacking a loop on the wall or ceiling and using a coupler such as SGC-230 or putting up a flagpole or a dipole in the attic. Inverted L along roof edge may work also. I don't think putting RF on the house AC wiring is the way to go! That Dovetron thing was very expensive also!

>
> Is the TS850 built in ATU likely to provide a reasonable match on all
> bands in this configuration?

No. I am not familiar specifically with the ATU in the TS-850 but most
of the built in autotuners are pretty well guaranteed to match an VSWR
of 3:1 at any phase angle and maybe 5:1 at some phase angles.

The beauty of feeding simple wire antennas with 450 ohm balanced
transmission line is that the VSWR on the transmission line rarely
exceeds 10:1 for a typical resonant wire antenna. For example, at 1/2
wl resonance, the feed impedance will be around 50 ohms giving a VSWR of
9:1. At 1 wl resonance (so called antiresonance) the impedance is
difficult to estimate but probably less than 5000 ohms giving a VSWR of
11:1. Off resonance the VSWR can be higher than 10:1 but usually not.

Ideally, a 9:1 transformer would result in the VSWR on the 50 ohm coax
staying within the same maximum VSWR. Unfortunately, the ATU in the
transceiver lacks sufficient tuning range and may be damaged if tuning
into a very low impedance is attempted.

> Any better ideas for multiband 80-10m operation?

Consider the so called Maypole consisting of multiple 1/2 wl dipoles
radiating from a common feedpoint. The dipoles are in parallel
electrically and ideally connected to a current balun at the feedpoint.
The system is coax fed and with a little straightforward pruning can

easily be accommodated by the ATU on all bands which have elements.
Usually the 40 m element works ok on 15m if you are not too concerned
about the radiation pattern.

You are likely just showing a bit of coupling between the 40 and 20
legs. Maybe spread them apart a bit farther. If you have a small tuner
you could just use it to get a better match on 15. The feed impedance
will be fairly low, and the loss fairly small. If I had a tuner around I
would use it instead of trying to tweak the wires to work 15 better. I
doubt you would notice the difference on the air between using a tuner
and not using one for that band. MK

Start by checking if there is any grass touching the fence. If so,
trimming the grass will stop a lot of the irregular noise pulses. An
electric fence operating correctly, will be a regular pulsing noise.
Diplomacy works lots better than your other recourses. Also might
tell the owners that the noise the fence produces is wasted
electricity
so that it would be in their favor to make sure the fence is working
correctly...

Brian,
The 850's tuner may or may not tune the antenna. I wouldn't
count on it. Some bands are going to be out of range for the
ATU. The manual tuner is probably going to be your best bet.
About the balun. The 4:1 should work fine. So should any
of the other ratios. The actual impedance of the antenna system
is not going to be close to 450 ohms, except by accident.
Ladder-line/open-wire feed lines really aren't that 'touchy',
bringing it into the caravan through a window should work as well
as using the balun and coax feed line. No idea if it would be
any 'better' than how you plan to do it though.
Good luck...

I addition to K1BQT, let the farmer know their is a problem first and give him what you think it might be and it is unlikely he will have to invest in a new controller. Let him know you are willing to try to isolate the problems spots and work with him in correcting them. You are more likely to know how to make a connection electrically more secure than he might think might be necessary. If it weeds, let him know it is just as eerily for you to pull them if it a small isolate spot. A little good will should bring a more favorable response. But you don't just want to trespass on his property and then call him with all of the problems he needs to resolve. If he basically say get lost, write him a simple direct letter that their is a problem and if he reviews the documentation on the controller that he is responsible and you are still willing to work with him to find the problem(s) to help resolve them. If this does not work, send a formal complaint to the FCC with what you have done so far and cc him. If you get to this point, you also may want to give the local police/sheriff a heads up about the problem and that you have not entered his property and will not unless invited to circumvent a false trespassing complaint and are only trying to work in the spirit of cooperation.

Hi Scott,

The capacitor is the heart of the indicator circuit. It holds the rectified over the air signal while the multi-meter presents the reading of voltage as an indication of the field strength.

I presume you mean to use the FSM to measure the effective output of the AM transmitter. You should only need to increase the inductance of the inductor L1 in the FSM to roughly the same value as the component T1 in the transmitter. This is not a strict requirement however as the current FSM design may have enough sensitivity to work for you anyway (but it would work a whole lot better with more windings in L1). The reason for this difference is that the two circuits operate at vastly different frequencies. Even so, at close proximity (within 20 feet), this shouldn't matter.

1231. Receiving antenna question re 'matching' random wire.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-29 00:00:00 UTC
From: Terry Sanford <tsanford@roadrunner.nf.net>
Message-ID: <39ABE65C.C72C627@roadrunner.nf.net>
Source record: 181561

I've erected a random approx. 60 foot wire for short wave; receiving only. It's about 25 feet high and as clear of buildings and overhead utility wires as I can make it.

The wire material appears to be plated steel. What it actually is is the support wire/strand from a scrapped length of cable TV coax! We just peeled it away from the coax complete with its insulating plastic covering. It's light, strong and relatively inconspicuous.

This antenna will have many different impedances at various frequencies? I would like to use a coax lead in to my basement shop to minimize electrical RFI so I propose to use a Hi/Lo untuned matching device.

I propose this:
Provide an untuned inductance/coil between the antenna wire and ground, outside where it connects to the coax. I propose two taps on the untuned coil; one at say 10% of turns to give a 100:1 impedance match the other near the 'top end' of the coil for those frequencies where the antenna has a relatively low impedance. There will be a remotely controlled switch or relay to switch the centre conductor of the coax between the two taps. I will probably use some RG8 or RG58 for the approx. 40 foot lead in and connect it to the balanced doublet terminals of my receiver rather than the high impedance capacity coupled 'open antenna terminal'.

This, I guess, would be called an aperiodic (untuned) auto transformer. I first saw reference to 'aperiodic transformer' in "Practical Radio Communication." McGraw Hill, 1943. In fact such an arrangement with a fixed low impedance tap is shown in the text with wording "A standard antenna-coupling transformer is used .....".

The single coil will also incidentally keep the antenna grounded; for safety, as recommended for transmitting antenna and or for static discharge. Not that lightening is much of a problem here.

BTW I have exchanged emails regarding using using steel cored clothes line as an antenna, with a ham who is in Scotland!. His application is the relatively narrow bands of frequencies for each amateur band; whereas mine is for receiving all shortwave frequencies.

Any comments/suggestions please.

Regards. Terry S.

1232. Re: Is there an effective 75 meter mobile antenna?

Newsgroup: rec.radio.amateur.antenna

Source record: 181562

In my model, the horizontal components pretty much cancel out, so there's no significant horizontal component. As I mentioned, assymetrical mounting would produce an uncancelled horizontal component, but it would be close to the ground, so would be the source of substantial loss, and would radiate a relatively small amount, mostly straight up. I haven't confirmed this by modeling or measurement, though.

It looks to me like a 5 foot high vehicle will radiate as much as a 5 foot vertical wire with some top loading (as much top loading as required to get about a 2:1 current ratio at the ends), provided that the antenna is placed at the center of the top of the roof. Likewise, a 6 foot high vehicle will radiate as much as a 6 foot wire, and so forth. I believe this would be true regardless of the relative width of the vehicle.

This is a 'studied' response to the apartment antenna a question.

Is it possible to poke anything out of the window. Such as long fishing pole with metal filament line. If and ever someone complained or asked about it could you say that, " you were just 'drying it out'; why is there a problem?". Or "trying it out"!,

Of course maybe you could wind a big coil around the whole apartment, or one room and excite the whole building as one big antenna! Or could you give one end of a really, really; really fine wire (so fine, off an old transformer, that you can hardly see it) to a friendly squirrel and ask it to run up an adjacent tree? If it breaks and falls down from the window it can be attributed as being part of a fallen experimental kite that blew into town! or somesuch!

Idea!

I didn't say it was easy... keep experimenting. I wound up building
a jig to hold the thing steady against pressure from an exacto. Still
came out sloppy. Try replacing it with a shorter button from another
(dead) watch if it really bugs you.

Also try a Dremel or similar. Rough finish, but much better
look/feel.

For a fan dipole, more the one leg connected at common feed point, when used with 50ohn coax at the ffed point, do you need a Balun at the feedpoint? 1:1 or 4:1?

Chip et. al. have gotten so much crap from "innocent querents" that
they tend to lash out a lot, which naturally leads to a positive
feedback loop like what you wrote just above. Perhaps a bit of stress
management therapy for them is in order.
Sorry if that sounded like a slam Chip and Co., but please don't die
from a heart attack just yet. The fractal antenna concept _is_ valid
and needs more work to convince the doubters. If you die now it will
sit on a shelf for thirty years or so and the "rediscoverer(s)" will
get all the credit. Also, we'll have to wait longer for the
applications to come online.

Chip, read George O. Smith's _Venus Equilateral_. Most corporations
are run by lawyers who hire technical talent, and the lawyers tell the
techies what to invent and when to do it. Smith saw that a technical
businessman should stick to the tech, and hire lawyers to advise him
how to protect himself. Sounds like good advice to me.

> other threads as you guys discuss in great depth antenna theory.

New ideas, especially when presented by somebody who _dares_ mention
the concept of making money from them, generate trouble. That annoys
some Hams, but fractenna always made it clear that as is true with any
patent, building examples for experimentation is free. OTOH, a lot of
so-called Hams here seem to want to own a setup straight from the box
and don't care what's going on inside the shiny cases. Bending wire on
one's own is just too much trouble, I guess. (Some time ago I
mentioned that Hams used to be expected to be able to make their own
tubes if they had to. What happened to that kind of guts?) Besides,
if somebody finds something Chip et. al. didn't notice, they just
might get their _own_ patent.

> I've been on other newsgroups, and sometimes there is someone out there

I hope the casual reader doesn't infer from this that cosmic rays are the same as radio waves. They're similar only in that they're also electromagnetic waves, but they have very different characteristics because of their much, much higher frequency and energy. Cosmic rays are ionizing radiation, like X rays and gamma rays. Radio waves are not, so they have a very different effect on the body. Ionizing radiation is the stuff of nuclear explosions, with well known bad effects, while so far the only firmly established effect of radio waves is heating, and it takes a very large amount to noticeably heat a body. (This effect is seen daily in microwave ovens.)

But, even if you got far from civilization, you would still be bombarded with radio waves (as well as cosmic rays). Some originate in space, from the Sun, stars, and planets. Others come from terrestrial sources like lightning storms. You just can't leave home without 'em.

>
> kf4oua

No more or less than you need a balun with any other dipole. Without a balun, current will flow along the outside of the coax, making the feedline part of the antenna. It's the job of a balun to reduce this current. The amount of current that flows depends on the length and orientation of the feedline. If the current is small, a balun won't do much. But if it's large, it can have a number of unpleasant effects. Your SWR can change when you move the feedline or change its length. You can pick up loss due to the feedline lying on the ground. RFI can be aggravated if the feedline runs close to power, telephone, or other wiring. And you can have "RF in the shack". Feedline radiation will also modify the antenna pattern, most typically moving or filling in pattern nulls. Some hams, including me, routinely use a balun for added insurance that the antenna will act as intended, but lots of others happily take what they get.

A 1:1 "current" balun would be the appropriate one for this application, since you don't need or want an impedance transformation.

1994 Pontiac has an antenna with noticably worse gain (AM band) than the

Dodge sitting next to it. Gain on the Pontiac increases discernably
when
someone touches the whip, while holding the Dodge's
whip makes no noticable difference.

Lead-in continuity and ground points have been checked, etc.

Pontiac has Antenna at the rear, so probably about 15 feet of leadin,
while
Dodge is maybe only 3.

Anybody have an idea how to correct the gain in the Pontiac Antenna??

1245. Re: Auto Antenna Problems

If the antenna is a magnet mount, try moving it to the center of the roof, or running a ground strap between the trunk lid and the body of the car. Your problem might just be a small groundplane.

By the by, what did you mean by leadin? Coax?

Art Leganchuk wrote:
"Anybody have an idea how to correct the gain in the Pontiac antenna?"

Auto radios depend on resonance of the antenna circuit for performance.
If the antenna trimmer adjustment is off resonance, sensitivity suffers.
Try optimizing the antenna trimmer.

PacerAl wrote:
"For a fan dipole, more than one leg connected at common feed point, do you need a Balun at the feed point?"

A fan dipole may couple more energy into its feedline because of the difficulty of making the feedline perpendicular to all elements. A 1:1 balun may help equalize feedline currents.

Best regards, Richard Harrison, KB5WZI

1248. additional multiband dipole Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-29 00:00:00 UTC
From: Wayne Grauel <wgvideo@attglobal.net>
Message-ID: <39AC2186.7226B4D7@attglobal.net>
Source record: 181578

On previous multiband thread, Roy commented:
"No more or less than you need a balun with any other dipole. Without a balun, current will flow along the outside of the coax, making the feed line part of the antenna. It's the job of a balun to reduce this current. The amount of current that flows depends on the length and orientation of the feed line. If the current is small, a balun won't do much. But if it's large, it can have a number of unpleasant effects."
.....
My Question...

Roy, (and others)... would this apply to a G5RV (my only antenna) in a 2nd floor shack. I have coax going from my rig and tuner up into the attic, then outside and down the roof to the balun and twin lead feed line which is about 40 feet away from the exit point. the Balun hangs off the side of the house and the feed line loops up to the Dipole. I made my first contact on 10 meters the other night from MD to OK, but I'm still confused about grounding situations with an application like this. I doubt if I'm getting any RF because of the coax, but station grounding still confuses me. Some have said that a 2nd story shack is better off without a ground, because the electrical ground wire (chassis grounds) on any run of around 20 feet or so will actually be resonate and radiate RF. Is this correct.

Bye the way, the balun on the prefabricated antenna is sealed, meaning there is no coax connection, so the coax goes in one end and the twin lead comes out the other... the only RF connection is on the end of the supplied coax which is going into the tuner... I'm worried about lightning, though I'm tucked on the side of a hill with trees all around (much taller)... How does one protect a system like this?

From what I've read in the antenna handbook (the little one put out by ARRL) you ground the coax close to the antenna. Would it pay me to cut the coax close to the balun and insert some lightning protection and grounding device before it runs across the top of my roof?

Thanks,
Wayne

"I think" that there is a defacto copyright on e-mail. In other words you don't have to list it as being copyrighted, nor do I know of any cases where posting private e-mail has ever been challenged under that guise, but...

"As I understand it" posts fall under similar provisions in that other than the archives and the original groups to which had the original post, that reposting to another group is supposed to require permission. Also any repost requires that the original poster be given full credit.

However I would not use the word never as if I received a threatening e-mail I'd not hesitate to post it. Any one doing so would want to make sure that the e-mail fell within the legal definition of threatening, rather than their perception of being threatening.

>

Most writters will seek permission to use quotes from others work although it's not required if the author of the quote is given credit...but...one wants to be really careful that they are not using something out of context. Hence it's normal to not only name the source, but work and page as well.

Don`t step outside in the sunshine! For all we know, moderate r-f exposure is therapeutic. Remember the diathermy machines?

Ionizing radiation such as x-rays is known to produce ill-effects in relatively small doses if exposure is prolonged.

Radiowaves as used for communications don`t produce ionization and studies are inconclusive in linking cause and effect between exposure and physical changes caused by moderate exposure to r-f.

Saw some stuff about tuning automatically the Screwdriver style of antennas. Can anyone steer me to the company A&A Engineering who make the product Tennamatic?

Thanks

Hi Wayne,

From what you describe there's an even chance you already have everything in place and operational. A simple test would be to observe the SWR meter while you or someone else merely grabs the coax and moves their hand along its length (holding tin-foil is sometimes suggested). If there is any indication in change in the SWR then you have proof of currents residing on the coax's exterior which would then denote the failure of the BALUN to suppress them (one of its two operational characteristics).

This same test may suggest currents on the coax as a function of coupling of fields (this would suggest the dipole is not balanced, a different problem). However as the BALUN is responsible for snubbing conducted currents and not field induced currents, the difference would be one of magnitude (conducted currents would be greater than induced currents - except for the worst of balances).

Now, as to the topic of ground. You will note that nowhere in your antenna configuration is there any attachment to ground (aside from the ground lug on the tuner). If you were operating off of battery power, then you could reasonably be considered completely isolated from ground. This says nothing of safety considerations however which is a topic that is often co-mingled with RF Ground but is not the same thing. You could probably operate quite well without any other attachments, but it would still be a lottery every time a thunderhead moved over you.

If you were to remain battery operated, but used that ground lug to connect to earth ground; then some current may develop on it on the basis of the dipole's balance with respect to earth. This would satisfy some safety concern but would have no bearing on operation except to the extent of imbalance of the dipole.

If you were to switch over to the mains supply (through a power supply) then you would observe some ground path finding its way into the system (if only through the metal chassis and the commonality of power and RF grounds within each piece of equipment). AND If you were to also add that wire to earth ground to the lug in the back of the tuner; then you may become victim to the ground loop. This may be resolved if both your earth connection and the mains' ground were tied together, but even here there is room for RF to present interesting (but annoying) currents. The solution to this last incidental ground arriving through the mains is to break the path with an isolation transformer (with careful attention to isolating the input from the output - this generally is performed with a Faraday, or electrostatic, shield between the windings and separating grounds). The co-mingling of grounds is the greatest source of grief for many operators (even pro's).

Most safety solutions that are incorporated into the antenna system provide for some path to ground (you supply the real path however, and it better be a direct path to a good ground). However, this introduction of ground is in itself isolated until some incident (the lighting stroke or EMP) and it does nothing for your RF ground needs

(which for you approach zero). Keep in mind that moving the arrestor towards the BALUN only increases the length of the ground wire that would be used to drain the lightning stroke. You want to minimize this length and having the arrestor at the BALUN does not serve that purpose unless it is physically closer to the ground point than other alternative attachment points.

Hi Roger,

Interesting spin on this topic. It is revealing how one can complain
of intellectual rights being trampled while violating them at the same
time. Of course the all encompassing "moral outrage" can be put to
use to justify any action - even if it is morally outrageous.

However, the fact that e-mail is the least secure medium for
intellectual rights, presuming any protection is laughable. On the
other hand, simply because no real protection exists is not an
imperative to violate rights in these same fanciful moral crusades.

Morality. To paraphrase Dr. Johnson (LLD), "moral outrage" is the
last refuge of a scoundrel.

I don't have the data at hand, but it should be good for any power the
coax is rated for that will fit the connector. I have ran over 50 watts
with this combination without any problems.

> Long Wire outside
> but getting back into the house seems like it might be a problem????????

I wouldn't want it lying flat near any extended area of metal. But I
have tried closing an aluminum window on ladder line, and it didn't
really effect it much that I could tell. The window bottom kinda knife
edged and being it dropped down at an even angle to both conductors it
was balanced and a very short distance. Seemed ok.
But I wouldn't want ladder line lying flat against metal siding. I'd use
standoffs. To do it right, I'd also use an insulated window section for
the lead-in, but being I had no troubles, I didn't bother. It will work
with the window just closed down on it. Of course, you can't fully
close,or it will mangle the line. I just let the window down the that
level and stopped. Used a piece of foam to insulate the large crack at
the bottom. MK

Terry Sanford wrote:
"I will probably use RG8 or RG58---."

Why not use RG-11 or some 75-ohm TV cable to connect with your receiver. The receiver doublet input likely anticipates 75 ohms and this would be a slightly better match for your antenna on most frequencies.

Plated steel wire is as good as the plating depth and conductivity for antenna use. R-F penetration is slight, so the steel is not usually relevant.

Best regards, Richard Harrison, KB5WZI

There's been a great deal of discussion about this antenna in this newsgroup on many occasions. About every couple of months someone asks the same question as you just did, and people respond with a wide range of opinions. What they boil down to is whether you value the ability to apply power to the antenna without tuning more than you value radiating most of the power you do apply. I suggest doing a search of this newsgroup at www.deja.com. You'll find a wealth of postings on the topic.

Terry Sanford wrote:
"I propose two taps on the untuned coil---."

A better scheme to avoid noise pickup on the feedline may be to use an isolated secondary of a few turns without direct connection to either antenna or ground to attach your feedline.

Noise will become common mode and balance out in the coils at either end of the feedline.
When your reference was published, this would likely have been twisted pair, but coax will serve the purpose.

Scott Mann wrote:
"How does this circuit work?"

The publisher of the circuit could not supply it when I addressed the URL.

All field strength meters receive the signal and display a strength indication.

They are receivers of some calibrated sensitivity, large or small, depending on the particular use. To give good results they must be used with a particular antenna and operated under defined conditions. They often contain a calibration oscillator to set the sensitivity for accurate measurement.

Don`t have the circuit, so the capacitor function is unknown. I`ll guess that it was some variable type either used to set the frequency or sensitivity of the meter.

A G5RV is tougher, because a balun will work only when the impedances involved are reasonable. In an antenna like the G5RV, the impedance can vary a great deal from band to band, so the balun might not be effective on all bands. About the only solution, if you want balanced feed (that is, no current on the outside of the coax, or no common mode current on a two-wire feedline) is to use a balanced tuner or link coupling. Or you might be able to get a reasonably low common mode current with a combination of balun and fiddling the feedline length.

Mutual coupling from the antenna will also cause common mode current, and in some cases more than one balun is necessary to reduce the current to a low level.

If you have a properly functioning balun (hard to do on all bands with a G5RV), the current going into one of the feedline conductors equals the current coming out of the other. Then there isn't any left to go to ground, and there's no need for an RF ground connection at all. If, however, you do have a common mode current, an equal current will flow to ground by whatever path it can take. You'll want this path to have a low impedance. If you're reasonably close to an Earth ground, a large conductor or wide strap connected to several shallow-buried radials or even a metal water pipe where it enters the ground is probably adequate. If not, you might try connecting a quarter wavelength of wire to your rig and leave the other end open. This wire acts as the other half of the antenna being excited by the common mode current. If there's significant current, the rig should be "cold", but the other end of the wire will be "hot" and can have a fairly high RF potential. For something like the G5RV, you'd need one of these for every band where the balun doesn't do the job.

WARNING: These methods are NOT adequate or necessarily suitable for a lightning ground. Ground systems for lightning protection are a whole other problem. If you need one, you should carefully study the available information on the topic. A search of this newsgroup with deja.com will produce a lot of good information.

However, flat conductors have less inductance for a given length than
circular ones, like wire. The better solution is to use a flat strip of
solid copper flashing. Less resistance, less inductance.

Hallo Tom, and also to Gray.
I wasn't recommending extremely short folded monopoles, and the Hairpin
Antenna really is an extreme case.
A short monople antenna will always have inherently small bandwidth,
regardless of configuration.

In most practical examples, ground losses will exceed the conductor losses within the antenna, and it is these ground losses which largely determine the overall efficiency and bandwidth of the system.
Bandwidth being inversely proportional to efficiency!
The advantage of the folded system is in the reduced losses in the matching networks which can be achieved using vacuum capacitors rather than inherently more lossy inductors.
For a given electrical height of monopole, the folded system can improve bandwidth by increasing the overall diameter of the radiator.
Perhaps one of the greatest advantages of the folded system is that it allows use of an existing grounded tower structure, and simplifies the connections to other antennas or lights mounted on the tower.

How much down is the horizontal pattern, and what band is this on?
Sorry to ask so many questions, but I don't have access to the
article.

Lets say you simply tie both conductors in parallel, and feed the
antenna as a marconi with a lumped inductor at the bottom.

Are you saying the bandwidth will always be wider when the antenna is
configured as a folded monopole with capacitors in the matching
system?

Are you saying the efficiency will always be higher also?

>Perhaps one of the greatest advantages of the folded system is that it

Now that is a true advantage. It makes running cables up the antenna
much easier.

I don't know for sure what freebanding is, but I assume it means
screwing up frequencies assigned to other radio services.

If you have a shorter antenna, base loaded with no capacitance hat at
or near the top, and it is broader in bandwidth than a full 1/4 wl
antenna of the same general thickness as the area above the loading
coil then the extra bandwidth comes from increased loss.

Thanks to all who responded. I have looked at the one site and it shows the exact antenna that I built. I will have to try it in that chunk of PVC tubing. Currently it is hanging unside down, with the feed line at the top, from the curtain rod in my room. Only 3" of the antenna are not in the window itself, but it is working somewhat better and my reports have improved. I will keep using it until I figure out what else might work. I will mess with it more when I have the time. Thanks again to all who have posted and e-mailed. I gives me something to think about when I am not studing.

Those would be the "big grip"? ends used with Phillistrand cable.
I use them and they are great, but you have to consider them disposable.
You can redo one of them twice, but not if they've been on for more than two
weeks.

With steel cable, I use the "wrap" method instead of clamps.
Again, the end becomes un-reuseable.

I've not used the ones you are talking about.

Possibly your've already done this, but:
Check to see if they are using tone access.
If so you might find that turning on the proper tone would even let your HT
get in...

Otherwise the repeaters may be running enough power so that you are hearing
signals that are being reflected and arriving in a direction other than
direct.
That's where the beam comes in handy.

It would almost certainly work better on top than on the trunk.
As to the radiation levels...I'd bet that the level is less than using the
HT "inside" the car and no where near the level when actually talking on
one.

I wasn't planning on doing any freebanding... just the normal 40
channels. I was just thinking that the larger loading coil would let the
loaded antenna be "closer" to 1/4 wave in physical length and thus not be
so funky to resonate.

Tom,,

Jack shows several plots.. Most are at 3.75 MHz. The maximum
horizontal gain is about minus 14-16 dB down from the maximum Vertical
gain and is somewhat perpendicular to the maximum total & vertical
gain.. (azimuth plots)..

Jack wrote a pretty good article you may wish to get a copy.

Hallo Tom,
I agree that the diameter of any mast or tower can be increased by using a cage of wires suspended by outriggers, and that will increase the bandwidth of the radiator regardless of mode of feed, however the folded antenna is a simpler system which no longer requires the complication of a base insulator.
I have never had a problem obtaining a 50 ohm match, even on a quarter wave tower, and often the matching component can be reduced to one component, i.e. a vacuum capacitor, with negligible associated loss.
I have had coils run pretty hot when using series feed on short masts where the feed resistance has been below 10 ohms.
Of course, it is always possible to use a bigger coil...
As to bandwidth, I once tried both systems of feed on a short top loaded vertical, about 300 ft, used on 252 Kilohertz.
The folded system gave noticeably better bandwidth, although both systems were pretty inefficient.
I guess you either like the system, or don't.
There have been many exaggerated claims made about the advantages of the method, especially in regard to ground losses.
Overall efficiency will always be determined by the quality of the components, and the extent of the ground system, but I do believe the folded monopole offers a simpler way to achieve this result at a lower cost.
As with any engineering problem, it all comes down to a compromise of performance versus cost.
Of course the folded system does modify the current distribution on the

mast, and that can be a disadvantage.....
I shall leave it there.
Best regards, Peter.

Thanks guys

I guess the G5RV (again) or Carolina Windom will be the antenna of choice for the day :-(

The maypole sounds interesting but not enough time to experiment before the weekend. I'm not sure that the contest doesn't dictate a max of 2 supports so even this might be a problem (unless we support in the centre and bring each leg in inverted V tethered to the ground with looong rope ends). Another variation would be to make multiband tuned dipoles out of ribbon cable - I'm assuming if the ends of the ribbon are separated so each dipole end droops down I'll get reasonable isolation.

Appreciate the confirmation of my suspicions that the original idea was a non-starter.

I, too, am puzzled by said comment. The bottom U of a J pole is not a 'phasing section' but a counterpoise. At HF it is not AS critical, and typically being off a few inches is not a problem. Perhaps that is what is meant.

Why do you need a J pole at HF anyway? Is it because it's easier to feed than a vertical dipole? It sure is huge!

Hi All

I just thought I would drop a line and mention that there is a good article on "An Iterative Model for Fractal Antennas: Application to the Sierpinski Gasket Antenna" in the May 2000, vol.48, no.5 IEEE Transactions on Antennas and Propagation.

The main author is Carles Puente Baliarda of Fractus (http://www.fractus.com). It does have some maths in it but is an interesting read nonetheless.

Anyway, just thought I would mention it.

Russell.

Hi Larry,
I put a Larsen dual band 2/440 glass mount on the driver's side rear window of my new Jeep a couple months ago. I put it about 3 inches from the top and about 6 inches behind the forward edge. On the MFJ antenna analyzer, it didn't look so hot, but in line vswr meter shows low standing wave on both bands. It isn't as hot as a mag mount on the roof, in that I have many more "marginal" areas into local repeaters, but it's good enough for my needs. Basically, the glass mounts are a compromise in favor of appearance, with a performance hit as a downside. I didn't get the MFJ dual band glass mount only because I felt it was probably even more of a compromise than the Larsen. But I'm probably just blowing smoke on that score...

Richard, thank you for taking the time to explain and shed some further light on my ground situation. I'm sorry to have been so confused on this subject (or just being plain dense).

Some have said that it is better to leave it completely alone, which I think in one case is what you're saying (lesser of two evils) ,

The balun which I referred to is located just at the end of the twin lead (about 15 feet long if I remember). If I were to connect a commercial lightning arrestor or protection device in the coax by cutting the coax and adding pl259's on the other side of the balun, that ground point would be about a straight shot 15 feet down to earth where i could sink a ground rod. Short of hooking it to the twin lead going up to the horizontal legs of the dipole, this is the closest point to the antenna, from a true earth ground (and outside of the house) and almost directly below it (with exception of the twin lead looping back up towards the end gable of the roof.

Do I hear you correctly, that the coax shield from the inserted ground protection (at the antenna location) running back to the tuner and rig, is totally isolated (not actually connected to the (earth) ground wire and therefore not an actual earth ground) until which point when lightning were to strike, the connection would be established and then bled off to ground and not through the remaining 75 feet of coax to the inside of my house?

Thanks again for your explanation, especially the simple test for RF in the shack... Great info.
Sincerely,

Wayne

>component, i.e. a vacuum capacitor, with negligible associated loss.
>I have had coils run pretty hot when using series feed on short masts
>where the feed resistance has been below 10 ohms.

That's where we disagee. While the capacitor is lossless, the entire
area of the radiator is now involved in higher VAR currents.

So instead of having losses confined to a few feet of coiled
conductor, you now spread the loss over a few hundred feet of
conductor. Indeed you can't feel or measure the heat, because it is
distributed over a large surface area.

This reminds me of the mind-games antenna manufacturers play, when
they say "lossless linear loading".

>Of course, it is always possible to use a bigger coil...
>As to bandwidth, I once tried both systems of feed on a short top loaded
>vertical, about 300 ft, used on 252 Kilohertz.
>The folded system gave noticeably better bandwidth, although both
>systems were pretty inefficient.

Did you measure the difference?

I'm not trying to be difficult, but rather to keep minds in touch with
the fact that spreading losses out doesn't mean they go away. And if
you have a given size radiator and you don't change the common mode
current distribution of that radiator, you'd should be very wary of a
bandwidth increase when opposite sign reactances from normal series
feed are added to the matching system. The trend of that is to
decrease BW, not increase it.

There's a lot of folklore imbedded in the folded monopole.

1293. Log Periodic Question.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-08-30 00:24:32 UTC
From: "T.G." <shbcommm@indigo.ie>
Message-ID: <6vYq5.19645$r4.10227@news.indigo.ie>
Source record: 181604

Hi,
I have constructed a log periodic antenna for the frequency range 100 to 1300 MHz.
It is nearly ready to install onto my antenna mast outside but I still have to attach the coaxial line. I copied the antenna dimensions from a friends commercial design and noted that on this antenna the coax line terminates in a small solid rectangular plastic block (approx 10mm high, 15 mm wide and 40mm long) with bolts protruding for attachment to each of the two main booms ie one for the 'active side and one for the 'groundplane' side. What I need to know is this - Inside that plastic block would there be some sort of impedance matching device connected accross the two bolt heads, ie a balun, coil or whatever? Do log periodics have this tye of matching normally? The coaxial cable going into this block is RG58 which of course is 50 ohms, so I also intend useing this type.

Thanks for your time.
Terry

>
>Cortland
>(ka5s@saber.net)

The small loop radiates because the sides have a spatial separation.
That alows a phase shift in space from one out-of-phase conductor to
the one opposite. It has no common mode current, or at least we don't
want it to have any. The normal direction of radiation is maximum
through the radius of the small loop.

The folded unipole (shorter than 1/4 wl) has significant "loop
currents", but the conductors are so close spaced (transmission line
distances) there is little radiation in that mode. The radiation is
pretty much all from common mode currents, which can be much smaller
than the differential mode currents.

Think of a short folded monopole as a loop that is too close spaced to
radiate, with all the losses of a loop of that conductor length and
current, driving a vertical with no loading system.

The inductance of the vertical feed wires is in series with the
capacitors used for matching, VAR power and circulating currents are
actually higher than a conventional base loaded antenna.

Around 1981 or so I tried to convince someone to manufacture just such
an antenna. I had egg on my face when efficiency was measured, and it
wasn't from breakfast.

Looks that way to me also, assuming the vertical currents are the same
in the car body.

As I see it that means a 13' tall antenna above ground mounted in the
vehicle roof center works about the same as one mounted lower but
having the same above ground height, except for a little pattern skew
and a bit more loss from body to antenna coupling.

It's nice to know the car doesn't radiate real well, with a strong
horizontally polarized signal level like some texts claim. I think
this was the same conclusion reached a while ago when this was
discussed.

I guess I leave my antenna mounted on the upper corner of my truck bed
behind the cab, and not weld I- beams to the roof to support the
antenna.

I want to install my Kenwood G707 in my 2000 Chevy extended cab pickup. I'm considering trying the MFJ 2/70 glass mount antenna, but would like to hear from others about it first. I've heard that the glass mount antenna will not work properly on the tinted rear glass. I don't care if I loose a little efficiency due to the glass as I'm also concerned about looks. I'd like to here from others who have tried this type of antenna, especially on tinted glass.

1298. WTB: link coil sockets, pins, etc.

I thought the UK held the European Prize for bureaucratic over-
enforcement, but we'll gladly hand it over.

The German regulatory authorities have always been twitchy about
radiation hazards, and maybe they're trying to kill the radhaz bird with
the RFI stone.

>There are certainly some disadvantages to voluntary immunity standards, but
>at least with them in place, everything is negotiable. If the regulatory
>alternative is applied both ways, the manufacturer has every leg to stand on
>and the ham must demonstrate 3 V/m in his neighbors homes.
>

It doesn't have to be as bad as that. Once the regulations have forced
designers to think about EMC, most equipment exceeds the immunity
standard by a significant margin (there are still problems with imported
junk that doesn't meet standards, but that makes it illegal which gives
us a negotiating advantage).

In the UK, most problems with RFI from amateur stations are solved by
finding and fixing an installation fault - usually in the receiving
setup. The immunity standard would only be invoked if all other cures
had been tried and failed, and excessive field strength was the *only*
problem left.

I don't know whether, on balance, it would be better if the European
regime was the same as in the USA, or t'other way around... but that's a

moot point - none of us has the luxury of being able to choose.

So does my stacked 2-meter array at 130 feet, but that is not taken into
account in the calculator I used to figure the exposure. They figure the
height, but it appears to only be used for calculating distance.

I cover the entire 75/80m band without a tuner by varying the
length of my ladder-line from 90ft to 110ft.

> any suggestions?

Laid down, the J-pole looks like this:

```
<--1/4WL--><------1/2WL------->

+---x-------
|
+---x---------------------------
```

With the bottom 1/4WL stub shorted, you can get any impedance
between zero and a few thousand ohms by moving the feedpoint
(x,x) up or down. (up or down is right or left in the above).

Mark:

There has been some interesting research of late about how low audio
frequencies (under 20 Hz) can affect the state of a human being's
mind, making them feel a bit light headed, perhaps more open to
environmental stimuli, or higher planes of existence (if you believe
in that sort of thing), perhaps as you describe. Maybe there is a
correlation with HF RF?

I'm no expert in the field, I'll readily admit that, but it's at least
food for thought.

I could see how an ordinance requiring only hands-free use while in motion could reduce accidents, but how are the States able to improve the quality of VOX/audio in cell phone models? The manufacturers have shown to date *extreme* reluctance, one might even characterize it as contempt, to suggestions from governement and citizen watchdog groups to improve their products. It was only when then were *compelled* to do so very recently that they began publishing RF emissions/exposure data from their products, protesting that coonsumers will be scared off without technical merit, ignoring the fact that maybe some of us might like to know what the EIRP from a given phone model's antenna is. That is useful data in choosing a phone, apart from any aid in evaluating the likely hazard to eye, ear, and possibly brain tissue, from poorly designed/situated collapsible antennas

I haven't been in to a shop to look over new phones and their packages, but I don't see that info anywhere in the ubiquitous print ads for service and portable units. No doubt it is printed in 6-point type somewhere in the back of the manual, right below the copyright info and corporate address.

Unfortunately, as is almost always the case now, it is probably going to take a number of high profile fatal accidents before anything happens with regard to driving safety, on the scale of the Explorer/Firestone debacle.

I guess what puzzles me most about the issue is why the use of dual-band mobiles by hams, and mobile hand-mike PTT-operated radios in general by all users hasn't caused more accidents, and cell-hones have? The only thing I can think of that makes sense is the differential in training and attitude between the typical cell-phone user and the typical mobile radio user. Cell-phones have become universal so suddenly, that we have adopted them so fast thaat we haven't had time to adjust to the split in attention. Most people just combine the two activities--driving and phoning--without a thought. Cell-phone use is casual and almost compulsive. Mobile radio usage is more structured and formalized, and we have been doing it a lot longer. I suppose it is also the case that you can hold the mike while still having both hands on the wheel, while listening. You don't have the thing jammed in your ear, tying up one hand all the time. A little care and attention and common sense would go a long way. I am not holding my breath--I just affixed a fresh "Hang Up and Drive!" bumper sticker.

Which is to say, a non-solution. Having better waulity ahnds-free units
on the market might help out. An aggressive "education" campaign by
police also could help, if they vigorously looked out for and stopped
drivers who they see talking on the phone and drifting, weaving,
speeding up/slowing down, changing lanes for no reason, leaving blinkers
on or using the improper indication. A little lecture and
warning--backed up with the threat of a ticket, 2-points minimum--will
make an impression on a lot of folks. I am not as grouchy as I seem--the
problem as I see it is largely one of ignorance and thoughtlessness, not
contempt and selfishness. Most drivers confronted with the facts of
their dangerous driving while on the phone, and the facts of the dangers
of phone usage relative to drinking, will modify their behavior
subtantially.

It's the newness and ubiquitousness of cell phones, in part. Give every 5-year old on the playground a full-auto M-16 with a 100-round box-mag, and turn them loose after showing them only how to reload, and see what happens. Hyperbole, I guess, but nobody has got it that you need to modify the way you drive and the way you talk on the phone, but mostly the way you talk on the phone. Instead of yakking, and driving, full-speed, around an accident scene or road crew, or likewise in a blinding rain, either tell the caller you'll call them back, and hang up until you have cleared the hazardous condition, or tell them to hold on and set the receiver down until then. No one seems to have the sense to do this, yet I see mobile radio users (ham and otherwise) do this almost always in such circumstances. It is experience, and training. Like the bumper sticker says: "Hang Up and Drive!"

Message-ID: <39B75493.43E70079@mindspring.com>
Source record: 181488

In a recent (sometime last Spring) study published in Science magazine, it was shown that 'incompetence' is the greatest bar to a subject not recognizing the fact that he or she is in fact incompetent.

Several groups of experimental subjects were tested (various IQ, achievement, and specific skill-set measuring tools were used) on their mathematical, musical, verbal, logical reasoning, visual-spatial, and social (listening, empathy, conflict-resolution, humor, assertiveness) skills, and then they were interviewed by psychologists and asked to give detailed self-assessments of their abilities in each of these areas, and to predict how they did on each test (in absolute terms [raw score] and also relative to other members of their group).

What they found was interesting, to say the least. Consistently, through several repetitions of this carefully designed, well-controlled study of over 1000 subjects (male and female, ages ranged approx. 18-75, cross-section of incomes, educationa; achievement, occupation, ethnicity) it was found that the subjects who scored in the bottom quartile (the bottom 25%) in a given assessment measure self-ranked themselves in the 70th percentile or above. It gets much more detailed and elaborate than this, if you are interested I will dig up the reference, I think they have it put up on a web page. But suffice it to say that the investigators concluded that by being low-skilled and incompetent at say, logic or conflict resolution, this incompetence leads people to over-estimate their ability grossly. The skills one needs to give an accurate self-assessment are precisely the skills that are lacking. This is why we have teachers and evauation tools for licenses, school admissions, etc. This is also why the dumb, climbsy, and thick-headed (not to mention the ugly) are so confident they are geniuses, and happily oblivious to reality. These researchers also found the opposite to correlate strongly--high-functioning subjects, those in the 90th percentile, almost laways ranked themselves near the 50th percentile (thus "average") or lower. Being smart, well-informed, and highly-skilled in a given area, or in general, seems to cause such people to have rational doubt (i.e. not neurotic ideas that "I am no good/no good at _____"). Intelligence and education breed healthy skepticism and the semand to be shown, to have a thing demonstrated and proved.

I will try to find the URL, or dig out the article and scan it, so that all who care to can see the psychology and social-psychology behind the behavior of some members of our newsgroup.

The difference is frequency, power level, duty cycle, and number of users/signals/antennas, and financial liability. Most hams aren't on the air 800 MHz, >800 MHz, 24 hours a day, unlike many commercial users. Commercial traffic, per base station, is usually much higher than a typical ham station. Then there is legal liability. Lawyers are out there, I am guessing but I am sure of this, literally cruising around with calibrated FS meters and OptoTrackers looking for antennas atop commercial and industrial buildings, and knocking on homeowners' doors. The FCC may be the least of commercial users worries.

BTW, there are a considerable number of dedicated VHF/UHF/SHF hams who have the calibrated FS meters, attentuators, RF voltmeters, and know hoe to use them to measure field levels and exposure, and are damn proud of the cleanliness, and safety of their stations. Knowing the math and RF engineering also will often eliminate the absolute need for $50K worth of specailized test gear anyway. Exposure meters aren't so much expensive, as a bit overboard, if you are only going to use them at one or two sites a couple of times. Simple tools and solid command of theory is perfectly adequate to get very accurate measuremtns.

Jeff,

Go to th Federal Communications Commision's web site, www.fcc.gov, and look up info on applying for a Low Power FM radio station license. The fee is very little, and you can get the coverage area you seek easily that way. It is a new program, just annopunced early this year, expresly for such community based applications as you propose. Be sure to get a license though--you can buy the equipment and get on the air without it, but the FCC is very aggressive in shutting unlicensed stations, even churches and community groups--down, and they can even levy a fine. Good luck, the proces is a lot easier and simpler than you might expect, and the equipment will set you back only about $2000 for a good professional set-up

This was on the antenna group,
Mike

You vulgar little maggot. Don't you know that you are pathetic? You worthless bag of filth. As we say in Texas, I'll bet you couldn't pour
piss out of a boot with the instructions on the heel. You are a canker. A
sore that won't go away. I would rather kiss a lawyer on the lips than be
seen with you.

You are a fiend and a sniveling, back-boneless coward, and you have bad breath. You are degenerate, noxious and depraved. I feel debased just for
knowing you exist. I despise everything about you. You are a bloody nardless newbie twit protohominid chromosomally aberrant caricature of a

coprophagic cloacal parasitic pond scum. And I wish you would go away.

You're a putrescent mass, a walking vomit. You are a spineless little worm
deserving nothing but the profoundest contempt. You are a jerk, a cad, a

weasel. Your life is a monument to stupidity. You are a stench, a revulsion,
a putrefaction, a big suck on a sour lemon with a lime twist.

You are a bleating foal, a curdled staggering mutant dwarf smeared richly
with the effluvia and offal accompanying your alleged birth into this world.
An insensate, blinking calf, meaningful to nobody,
abandoned by the puke-drooling, giggling beasts who sired you and then killed themselves in regret for what they had done.

I will never get over the embarrassment of belonging to the same species as
you. You are a monster, an ogre, a malformation. I barf at the very thought
of you. You have all the appeal of a paper cut. Lepers avoid you. You are
vile, worthless, less than nothing. You are a weed, a fungus, a ferment,
the dregs of this earth. And did I mention you smell?

If you aren't an idiot, you made a world-class effort at simulating one.

Try to edit your writing of unnecessary material before attempting to impress us with your insight. The evidence that you are a nincompoop will still be available to readers, but they will be able to access it more rapidly.

You snail-skulled little twit. Would that a hawk pick you up, drive its

beak into your brain, and upon finding it rancid set you loose to fly briefly before spattering the ocean rocks with the frothy pink shame of your ignoble blood. May you choke on the queasy, convulsing nausea of your own trite, foolish beliefs.

You are weary, stale, flat and unprofitable. You are grimy, squalid, nasty and profane. You are foul and disgusting. You're a fool, an ignoramus. Monkeys look down on you. Even sheep won't have sex with you. Your hand even refuses autoerotism. You are unreservedly pathetic, starved for attention, and lost in a land that reality forgot.

And what meaning do you expect your delusional self-important statements of unknowing, inexperienced opinion to have with us? What fantasy do you hold that you would believe that your tiny-fisted tantrums would have more weight than that of a leprous desert rat, spinning rabidly in a circle, waiting for the bite of the snake?

You are a waste of flesh. You have no rhythm. You are ridiculous and obnoxious. You are the moral equivalent of a leech. You are a living emptiness, a meaningless void. You are sour and senile. You are a disease, you puerile one-handed slack-jawed drooling meat slapper.

On a good day you're a half-wit. You remind me of drool. You are deficient in all that lends character. You have the personality of wallpaper. You are dank and filthy. You are asinine and benighted. You are the source of all unpleasantness. You spread misery and sorrow wherever you go.

I cannot believe how incredibly stupid you are. I mean rock-hard stupid. Dehydrated-rock-hard stupid. Stupid so stupid that it goes way beyond the stupid we know into a whole different dimension of stupid. You are trans-stupid stupid. Meta-stupid. Stupid collapsed on itself so far

that
even the neutrons have collapsed. Stupid gotten so dense that no
intellect
can escape. Singularity stupid. Blazing hot mid-day sun on the warm
side
of Mercury stupid. You emit more stupid in one second than our entire
galaxy emits in a year. Quasar stupid. Your writing has to be a troll.

Nothing in our universe can really be this stupid.

Perhaps this is some primordial fragment from the original big bang of
stupid. Some pure essence of a stupid so uncontaminated by anything
else as
to be beyond the laws of physics that we know. I'm sorry. I can't go
on.
This is an epiphany of stupid for me. After this, you may not hear from
me
again for a while. I don't have enough strength left to deride your
ignorant questions and half baked comments about unimportant trivia, or
any
of the rest of your drivel.

The only thing worse than your logic is your manners. I have snipped
away
most of what you wrote, because, well... it didn't really say anything.

Your attempt at constructing a creative flame was pitiful. I mean,
really,
stringing together a bunch of insults among a load of babbling was
hardly
effective... Maybe later in life, after you have learned to read, write,

spell, and count, you will have more success. True, these are
rudimentary
skills that many of us "normal" people take for granted that everyone
has an
easy time of mastering. But we sometimes forget that there are
"challenged"
persons in this world who find these things more difficult. If I had
known,
that this was your case then I would have never read your post. It just

wouldn't have been "right". Sort of like parking in a handicapped
space. I
wish you the best of luck in the emotional, and social struggles that
seem
to be placing such a demand on you (like passing gas, for instance).

In short, if I traded you for shit, I would lose the container I brought
you
in. Otherwise, have a good day.

Thread:

Hey, I love the ARRL as well as the next ham, been a member for over 30
years, but "leadership" has been sorely lacking.

We need to learn from the NRA about how to be an effective special interest
group, we need to elect someone like Chalton Heston as the President of the
ARRL, maybe then "we the people" will get to keep the spectrum that we
already own!

Hi Will,

That's an interesting report, and probably explains some of the
behavior we see from our resident newsgroup Dr.

I always assumed he was basically a bright fellow, who stood in his
own way with an inability to exchange information with others. I
thought that was mostly due to an overinflated ego.

Something else is going on, however, because he does a quick back-flip
when some appears that might be able to do him a "favor". Check out
his behavior change now that someone new has appeared on this NG.
Suddenly he is all smiles and other AOL-type Internet Mary Poppins
protocol.

Your report may be right on target.

Microwave is very much below the level at which individual photons have sufficient energy to ionize atoms; in what way is their interaction with matter determined by quantum mechanics?

>photon absorption in water molecule spin states occurs
>one cannot excite a quantum-mechanical transition with photons of
>insufficient energy (frequency) no matter how many one uses (how much power)

Exactly, which is why the absorbtion is purely a matter of heating
.
>the meat may very well cook by other means (currents), much less
>efficiently,

If something is inefficient at turning energy into heat, does it dissapate the ineffeciency as heat? :-)

>but there's a reason for the microwaves, and it's to spin the water molecules

There is no peak near 2.4 GHz in the absorbtion of RF by water vapor in the atmosphere; the peak occurs much higher in frequency. But I would certainly be interested in reading about any published papers about the spin of water molecules by microwaves; can you provide some references? In this area, I certainly have a lot to learn.

>but how many physicists are in this debate among biologists
>who know little of the interaction of radiation with matter
>and lawyers, who know even less

The IEEE committee developing standards includes a wide range of people. Among those people and among the papers being evaluated for future revisions of the standard are physicians, researchers, physicists and even a lawyer or two.

>interference to and from my ham radio and dbs video distribution equipment
>(it's on 2.4 gig).

I have one report so far of harmful interference to ham radio from high-power 2.4 GHz wireless internet. In that case, the provider actually shut down the offending channels to protect over-the-air service.

I think it unlikely that your transmission will cause damage to their system, but in all proabability, it will bring it to its knees when you are on the air. Under Part 15 rules, they need to accept this interference from a primary user.

I very much want to hear any and all reports of interference to hams from Part 15 devices. Two ARRL Board committees are studying the problem and I want to send them any actual cases.

See http://www.arrl.org/tis/info/part15.html for info on Part 15.

If you look at the spectra of various transitions in the atmosphere you see that the spectral lines are very low Q and extremely spread out in frequency. This is caused by collisional broadening.

The reason this is relevant is that water vapor need not be exposed exactly at the 22.235 GHz transition in order for energy to be absorbed, but can be absorbed at frequencies substantially lower.

If quantum mechanical isssues are raised here, let's bring in all the salient effects.

>Fact is if you only have a few radials, try to make them resonant and
>keep them away from earth. A marginal ground system can make a
>vertical...especially a short one....loose more than 10 dB of signal.

Even if one could put up 120 half-wave buried radials, often considered to be nearly a perfect ground, the low-angle performance of that vertical is determined by the characteristics of the ground at the point where the reflected ray at the correct downward angle from that antenna reflects. That could be a very long distance from the antenna for very low angles. If he is over an area of poor ground, the vertical may not be a good DX antenna.

That may explain the adage that a vertical antenna is an omnidirectional antenna that radiates equally poorly in all directions. That does NOT apply to vertical antennas with low ground losses that over over very good grounds; in those cases, the vertical does very well indeed.

The bottom line is that a ham is going to put up the best antenna that he or she can and make contacts. If that antenna were only 5% efficient (and it will be much better), it would be the same at the 5 W QRP station into a perfect antenna, and QRPers do it all the time. :-)

>

I thought about this a bit last night and decided to "take the challenge" so that you do not interpret my comments to be speculative and without some factual basis.

Here's one answer of many possible configurations that will have performance characteristics similar to or better than the MI2 Fractal Loop: A helical wound loop with a physical aperture size of 1/8 wavelength by 1/8 wavelength. The helical loop has a helical diameter of about 5 inches with about 20 helical turns per side. Using NEC4 to model the structure, it predicts the resonant frequency to be about 13.56 MHz. This is a lower resonant frequency than the MI2 Fractal Loop (I can change the configuration to match your resonant frequency but thought this to be unnecessary). The predicted resistance at resonance is 33.6 ohms which is closer to 50 ohms than the stated 26 - 30 ohms of the MI2 Fractal Loop. I won't state the antenna bandwidth because I do not know how you define it. Using my crude method of determining radiation efficiency, I predict it to be somewhere around 98% with number 10 wire. The predicted directivity and radiation patterns look very good.

I really have no issue with your claimed performance of the Fractal Loop. The only points with which I have an issue are the claim that the performance is only a result of the Fractal geometry, or that Fractal geometries offer optimum performance in antenna design.

Hi Donnie

The Copper Cactus is my copyrighted antenna plans!

The numbers you gave do not coincide with the Antenna Data for
Constructing the "Copper Cactus Antenna" which in fact uses the
standard wavelength formula x the K-Factor.

Your vertical element is slightly too tall and your stub is slightly
too short to achieve a balance.

Cut about 7/8 off the long vertical element, and install a brass screw
into the pipe cap on the stub and open it about 3 or 4 turns.

This should get it tuned pretty close to right on the money.

The legs of the matching section should allow a 2 inch ball to pass
between them, but this is not a critical measurement, so the 1-1/2
inches you used should be OK.

Yes, it's a "should do".

The problems with "if it works without a balun, don't fix it" is that by leaving the balun out, you risk causing RFI due to feedline radiation. It's liable to be your family and neighbors who find out if you need a balun or not. IMO that's an irresponsible attitude towards other people, as well as being lousy RF engineering. Prevention is better than cure.

The results of all antenna modeling programs are "predictions" based upon mathematical equations and assumptions about current distribution over small wire segments. My predicted efficiency is based upon an analysis (although a somewhat simplistic one). Perhaps I should have said "calculated". Would that have helped you any? Or better yet, how do you "predict" radiation efficiency?

You have not seen my NEC model and you have not seen the output files or the NEC calculated patterns. Given these facts, how could you even make a statement that I did something wrong in my calculations? NEC did the calculations, I simply prepared the input geometry. To make a statement that I did something wrong in my calculations without seeing the antenna geometry or the NEC results is presumptuous and arrogant. Do you always dismiss an other persons results and opinions simply because they disagree with you? The statements that you made above demonstrate a serious lack of professional integrity.

The difference is I can run 500 watts without owning a 500 watt tuner. Compare the cost difference between 20 feet of ladder-line and a 500 watt tuner. And I do the tuning from the operating position with the tweek of a couple of (digital) knife switches, easier than mucking with three (analog) knobs on a tuner.

How do you expect to be taken seriously by a professional community when your only position is "I am always right and everyone else is always wrong."

You have asked this NG to submit EZNEC models to you for evaluation. Why?? I state results of a NEC model and you dismiss them without even seeing the file with a statement "you did the calculations wrong - been there done that." Are you presuming to tell this NG and the antenna community in general that you have modeled every possible antenna configuration ever conceived or ever to be conceived and that your Fractal designs are the ultimate and best designs possible and that nothing else has or will ever will come close in performance? Your statements sure sound like this is your position.

Given your position, you should be willing to e-mail me your EZNEC model and let me look at. Will you or do you have something to fear? If you do, I will be more than happy to share mine.

Agreed. I think the gentleman was really asking for a usable antenna
as opposed to a contesters tuned for blood and guts style antenna.
My point was that even a very little bit of antenna, in this case
a ground plane with significantly less than the recommended numbers
of radials (to contesters or DXers), it would work well and allow
him to get a goodly number of QSO's.

My point in trying the enlarged 2M 2-radial ground plane was to see if
it would even work. It did, rather well.

Verticals, even simple ones, can and do work better than many folks would
say they do. I would consider them definitely worth trying, as opposed
to the usual dipole, and even in addition to the usual dipole. If one
can`t get the 200 radial monster set up, then even 1/2/3/4 radials can
suffice, rather well for most generic ham purposes. It may not be the
contesters or DXers most desireable vertical, but they do work and are
simple to throw up. A newbie or anyone wanting a good general purpose
antenna should seriously consider them, even simple ones. Oftentimes,
one does not need the blood-and-guts versions of a vertical, to get
perfectly fine and enjoyable ham operating.

Yep, but 20ft of ladder-line costs three dollars while a 500 watt tuner
costs 100 times as much. Seems like a no-brainer to me. :-)

Jeff,

I have used that type of balun, but only on 10 Meters and up.
I never even considered using it on that low a frequency because
of the sheer bulk. However, when I did use one it was usually for
matching between a folded dipole and a coax feed.

It seemed to work well, bringing the 300 ohm feed impedance of
a folded dipole down to around 75 ohms and converting the
unbalanced input to balanced.

I would think that the bandwidth would be a problem. A much
better choice is a nice broadband toroidal balun, if you really
intend to cover the whole band.

As long as you are still considering different types of wire
antennas, you might want to look at a broadband coaxial feed dipole
that is described in the 1999 ARRL Handbook. A more detailed
description, with all the formulas, is also in the Antenna
Compendium Vol 2 (or is it 1 ?? I forget.).

The antenna itself is actually a off center fed dipole that
uses coax as a matching element. The design is such that
the horizontal portion is made up of several sections of coax
and lengths of wire. It is fed directly with 50 ohm coax.

The one described in the handbook is for 80/75 Meters but
I made one that was scaled to 40 meters. Although I can't
attest to it's efficiency, it seemed to work very well.
For 80/75 Meters, the antenna had a very wide bandwidth.
My 40 Meter version is still in use, at a friends house.

1361. New Ham antenna questions....

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-07 14:59:21 UTC
From: SMB <scott.m.bowen1@jsc.nasa.gov>
Message-ID: <8p8ag5$p5a@niven.ksc.nasa.gov>
Source record: 181424

I just got my first rig, a Yeasu FT-1500M as a gift and I want to build a J-pole antenna. I live in a jack-booted thug subdivision that has antenna restrictions, so I figure a J-pole made from .5" copper tubing, painted flat black and mounted to a vent pipe on the back side of the roof should be OK. I made the antenna and I have some questions about tuning it...

Is there a good place to start, meaning, where should I put the connections to start with?

Are the J-pole designs hard to get tuned?

Does anyone have any other suggestions for stealthy antennas that perform well?

thanks,

Scott

> a perfect antenna, and QRPers do it all the time. :-)

Well said. Considering that most folks (aside from the diehard QRP types)
are going to run 50-150 watts, then even a less-efficient vertical, say
25-50% efficient, can put out a respectable signal and may be entirely
practical and acceptable to a given ham. Sure, it ain't perfect, but
it will work, and make lots of QSO's. The point is that one does not
always need the perfect antenna, even if it were available. Under
average conditions, +-3 or even +-10db is not a problem. If one can
hear it, one can usually work it (pileups and contests aside --- for
those you always will need the biggest bang for the buck horsepower).
Then there is the other side, too, that IFF I can squeeze one more iota of
ether out of the silly thing, I might go ahead and add another 100 radials.
That is a ham tradition of tinkering that goes back to the very beginnings.
It becomes a how serious do you want to get and how much are you willing
to invest into the thing proposition. I have gotten entirely acceptable
use, over the past 30 years on the air, of even the simplest sorts of
vertical antenna. You just gotta learn how to make them work. The
skill becomes in how you operate the thing rather than in the megadb
of signal you put out. But, I would never poopoo even a simple vertical
as being a lesser sort of antenna, compared to a dipole. My experiences
would rate them on an equal basis, with nuances associated with each.
On HF, a vertical is always a good bet in my book.

I live in Georgia, an area noted for poor soil. I have a 200 foot
tower with 100 200 foot (or so) radials.

I have a 318 foot tower, with a dipole (droopy dipole, ends are about
250 feet or so high).

In hundereds of A-B tests on 160 meters, the dipole and vertical are
either the same...or the vertical is a bit better. That's broadside to
the dipole, of course off the ends the vertical is substantially
better.

That was true at any distance beyond a few hundred miles, the main
exceptions occured during geomagnetic storms or at sunrise "peaks".

I had similar results on 80, with a dipole just under 1/2 wl high,
except the dipole was generally better within a thousand miles on 80.
Outside that, they were about even.

The worse investment I ever made in improving my signal was the 300
foot tower, but it turned out to be the most educational!

N6RK has done extensive comparisons on other bands. The data is on his
web page.

Never underestimate what a vertical a good system can do on the lower
bands!

Hi Rikki...

Please take a look at the field strength required to exceed exposure
limits.

One chicken little is enough, we don't need big bird chiming in with
needless warnings.

I might have a problem if I sat on a small loop antenna, especially an
ultra efficient fractal M-16 loop, but not with normal antennas.

I serious dounb't you could get enough RF back in your shack to from
the simple lack of common mode suppression on the feedline.

In the post-war era, "competitive mastery" was the dominant philosophy of education in this country. In the '60s, this philosophy changed, as social and political pressure built to promote "equity" and "positive self-regard" as fundamental values. Sadly, the Fed and pop psychology mainlined that approach right into the nation's classrooms through the 70s and 80s. The study Will mentions is often cited as a measure of our "success" in that arena!

How about building a 2 meter 1/4 wave ground plane antenna into a birdhouse
(build bird house around antenna) and then putting it up on a hollow
aluminum pole and feed the coax inside the pole. Do they allow bird houses?
Do you have and attic or dead space under the roof mount your antenna up
there.

thanks for the reply Berry!

Yup, I can do a birdhouse, and I have a tall attic, but I was concerned
about RFI in the house if the antenna is in the attic.

Is a 1/4 wave ground plain a great performer? I have heard and studied that
with 2m and other VHF-UHF, higher is better.

Thanks,

Scott

> rarely the case)!

Yes, it is rarely the case, but let's analyze a single nearly worst case to estimate how much of a problem this might be.

I just modeled the following, over average ground. A random wire with a 30-foot vertical section and a 120-foot horizontal section. In this case, the vertical section is as much a radiating part of the antenna as is the flat top. I used EZNEC to calculate the near electric field, at a height of 72" from ground, starting right at the vertical section and going out directly under the horizontal section. The controlled exposure limit is 61.4 V/m on the 10 meter band. At 1 kW continuous carrier, EZNEC predicts that the level of E field will drop below 61.4 V/m at a horizontal distance of 31 inches from the radiating vertical section. At 1500 W conversational CW, I calculate 600 W average power (1500W * 40% * 100% on/off time in 6 minutes). EZNEC predicts that the near field will drop below 61.4 V/m 24 inches from the radiating vertical element. If a ham runs an end-fed wire into his or her shack, this about the distance I would expect between the wire and the operator. Now, I chose 6 feet as a typical exposure height. The worst case E field exposure in this case turns out to be at a height of 16" above the ground. At that point, the required distance for 1500 W conversational CW turns out to be 47".

Keep in mind that this is really as bad as it can get. Though no feed line is "dead cold," would you estimate a pretty worst case *for cases where a ham is not getting RF in the shack problems* to be -10 dB? Dean Straw has done some EZNEC analysis of the common-mode signal in feedlines from badly unbalanced antenans and typically found them to be much better than -10 dB. But even taking -10 dB as a figure, the power radiated by the feed line would not be 1500 W conversations CW (600 W average power), but 60 W average power. This gives 20 inches compliance distance *at the worst point of my above model*, so even if a ham has a pretty leaky feed line, if is it 20 inches away from controlled exposure, it is okay. The uncontrolled limit is about 28 V/m, and EZNEC gives a required distance at 60 W average power of 37 inches for this really badly unbalanced feed line. At these distances, one is in the radiating portion of the near field, so the contribution from that nearest section of radiating feed line will decrease as 1/D. (The other sections of feedline and the radiating part of the antenna will add or subtract from that at any point; one is in the near field, but the point is that at the distance one must be to be below the limit from the antenna, a

badly radiating feed line is not affecting the RF at that point very much, as a rule.)

And, don't forget, that RF calculator is NOT the only factor that hams can use or necessarily consider. A ham who believes that feed line radiation could be a problem at his or her station should consider that as he or she does the needed station evaluation. The FCC has confidence that hams, individually, or collectively through discussions like this, will indeed consider the factors necessary to do a reasonable evaluation. I agree that feed line radiation could be a factor, but in light of the above analysis, I do not believe that the estimates from the various calculational methods of doing an evaluation are worthless.

> I think this RFI exposure thing is a bunch of hooey anyway.

At the levels of the standard, one does not expect to see problems. If the standard was set high enough that it wasn't hooey, I don't think it would be a very good standard.

>What I'm really griping about is my personal bias against simulations that don't include all
> the relevant variables.

Let's define relevant. If I use the RF calculator and determine that my neighbors need to be 33 feet from my antenna, and they are 133 feet from my antenna, have I not considered everything relevant? At 1/D for field strength, the feed line could not be contributing enough to push me over the limit. If I found I needed 33 feet and I had 34 feet between my antenna and my feed line was right next to my neighbor's balcony, I would know I had a bit more work to do.

>Or, perhaps I'm just coming down with a cold and feeling a little cranky today.

Rick Littlefield being cranky? Naw, could never happen. :-)

> Nice to see you contributing. The newsgroup seems to be more settled
> for some reason with you here, that's great.

I periodically look at rraa and when I saw RFI and RFX issues on the table, I felt I could make a contribution, so I chimed in. In many ways, with some of the names I recognize here, I feel I am in with some pretty knowledgeable folks, many of whom are a lot smarter than I am, so I stand to learn a lot and to more than once have someone add a lot to, or even correct, what I have to offer. I don't think any of us have all the answers and if people can add to, or correct, or even post opposing views, I feel that the value of discourse far outweighs my own feelings or even the risk of posting something that gets corrected.

As a young lady said to me once in a bar in East Hartford, one does not put the puzzle together by keeping all the pieces in the box. Sure wish it didn't take me so long to figure it out. :-)

As to "settled," probably a coincidence. I am no better at antennas that most, and less able than others, so I am just another ham playing in a fun forum. If I have brought any calm, it may not last; I will try to conduct myself in a way that honors the traditions of amateur radio, and discuss ideas, not personalities, but sometimes the presence of an ARRL staffer tends to bring out some bad things all on their own. I hope that folks will see most of my being here from time to time as personal; my boss does not ask me to get on various fora and enter into discussions, but he doesn't mind if I do (as long as I don't undermine my employer in the process).

But speaking of which, lunch break is over, so I will have to cut this one short, so I will pick up on the vertical/horizontal issue later. :-) Mark this one unread.

Hi Steve,

I heard this story on NPR this morning (it will probably repeat this
afternoon) about the LaBrea tar pits and how one animal would get
caught, attract a predator which would get caught, which would attract
a vulture which would get caught, which attracted flies which would
get caught....

You took up the challenge and got caught....

You may be surprised (perhaps not) how the replication of a fractal
design, which fully conforms or betters the original, is rejected as
flawed. This is apparently due to the extreme difficulty in realizing
a perfect(?) fractal design - or so one would be lead to believe if
such an inspecific claim of failure were to persist.

I can assure the readers that no such exactness is needed (unless you
absolutely insist on the poorer performance of the brand name model -
Chairman Bill has an operating system he would love to sell you).
Speaking of Chairman Bill, it appears that the FUD factor is alive and
well in the antenna design field (for non-computer folks FUD is an
acronym that applies to a marketing ploy of instilling Fear,
Uncertainty, and Doubt) - in other words, if the proffered design
fails some later revealed "purity" test, then it couldn't possibly
work.

My replication is deliberately non-pure, and as a consequence bested
the original (admittedly by negligible margins - much as the original
bests the comparison design... by negligible margins). The inverted
logic offered against the replication is that if the design is not
exact, then better performance is proof of failure.

This example fractal antenna, the k2, and a comparison design that is
infinitely easier to build within the same rectangular footprint was
also cavalierly dismissed as faulty. You can download both designs'

EZNEC files after viewing my data at:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
(Which the group will note is still available and unmoved in spite of protests and claims of action being taken to remove it - the FUD factor again.) You will note from this page that the near convergence of characteristics has nothing to do with the beingness of fractal. To paraphrase an old beer commercial: "It's the Ground!"

I've noted elsewhere that the limitation of a continuous wire has stymied some speculative entries. I find this an amusing commentary on the nature of the competition that tacitly admits superior performance from non-loop designs. Or could there be another reason why all comers that fit into the box are not all suitable challengers? No lumped lossy loads either. Odd that a competitor who would willingly accept the performance hit is automatically excluded from the meet. This probably discourages the use of Ground for optimization, but the rules appear to be silent in this regard - this may be a dangerous assumption for the naive entrant.

Perhaps this competition sieve is a 21st century form of the "science" of maxwellian eugenics and fractal "purity." As such it amounts to nothing more than a beauty contest (without the jiggle - DAMN!).

>No mention of power handling in the catalog.
>Regards, Jim

I don't think those numbers are correct. Type N should be the same as BNC, because the connecting surfaces are the same size (IE pin and shield ring) and spacing. BNC is rated to 500 volts. 500 volts is 5 kW in a 50 ohm system (P=E^2/R).

I know that N connectors will handle 5 kW PEP, because that's the power level of the driver stage in our older TV transmitter, and it uses N connectors for the semi-rigid line which couples it to the PA. It has been working for better than 20 years with no connector failures.

OTOH, type UHF connectors have been used by amateurs as HV connectors (not a good practice, but done anyway), at voltages up to 8 kV. So a rating of only 500 volts doesn't look right for them. The type UHF has a larger spacing than the type N and BNC, so it only seems reasonable that it would have a higher voltage rating too.

Ten dB isn't much if you only plan on working stations that are
strong, but even 1 dB can make or break a signal under less than good
conditions.

I think part of the misconception that 5 or 10 dB is not important
comes from looking at S meters, and assuming they are 6 dB per S unit
across the scale.

It takes very little work to move a vertical from a 5 or 10%
efficiency radiator, which it will be with a single radial laid on the
ground or just above ground, to one that is 50% or higher efficiency.

It's the pursuit of perfection in squeezing the last 10% out that gets
expensive.

1393. How to calculate wire equivalents of balanced feeders for EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-07 19:43:54 UTC
From: Jesper Wolf Jespersen <jwj@dde.dk>
Message-ID: <eeSt5.539$p1.7580@news.get2net.dk>
Source record: 181459

I have been playing with modelling my yard antennas with eznec and I would like to se what happens to a dipole when its equiped with a feeder.
I EZNEC one can easily model a bit of transmission line to transform impedances or what ever. But the model does not radiate, and a true feeder does radiate.
Especially antennas like the G5RV where the dipole is active mostly on the low bands and the feeder starts to act as radiator on higher bands cannot be modeled this way.

In EZNEC one can model these radiating feeders as the equivalent wires of specific width, at the proper spacing and the right length. But I dont want to sit and hand calculate these things when I am using a computer for modelling. There is far to great a chance I will make an error and not get the wanted results.

So what I am asking for is a pointer to a bit of software that lets me convert from transmission line to wire models, It would be particularly nice if parameters of know feeder lines where contained in the program.

Most feeders that I have seen consist of insulated wires and EZNEC does not model those, do any of you know what to do to build relatively correct models with EZNEC for these ?

It would be nice to be able to build an antenna like the one I model in EZNEC and having it perform like the model. I am not sure I will be able to determine in the field what translations from EZNEC to the real Life were right and whicn were wrong if an antenna does not even come close to modeled results.

I am still using a demo vesion of EZNEC but am considdering to purchase the full version.

What do the rest of you think of the program ?

I think its nice, but a better user interface where one could rotate a wire around an point or stretch a wire in the graphical display would be nice. Or simply a way to change from catesian coordinates to polar for wire specificatioin would be nice for some operations.
Again my point is that we are using a computer which is much less prone of dumb errors than the user is.

Imagine for example that you want to model what it means to add some ground radial to a vertical antenna.
Its trivial and not very interesting work to sit and calculate the positions of 4, 8, 12 or 16 radials of diferent lengths. Why not let the user interface program do all this.

After all EZNEC is just a user interface and data presentation tool. The calculations are performed by NEC-2 (or NEC-4 if you are really wealthy :-).

Maybe I should get used to running a spreadsheet for all these relatively simple coordinate transformations, maybe write macros for some of it.

What do you guys use ?

Greetings and 73 from Denmark

Jesper Wolf Jespersen

The attic would be the best place if there is room. I know a Ham that has
all of his antenna (dualband and a HF wire) in his attic.

Yes height is might, but if you are faced with antenna restrictions you do
the best you can. The 1/4 wave antenna is sufficent for local repeaters.

Good luck,

Barry D.

(on RFI problems)

Hams are a small part of RFI problems and solutions. As wireless grows at a much greater rate, hams will become even more insignificant.

Hams would be better served with creation of an attractive public image and an aggressive lobbying effort.

IEEE, SAE and all the others can manage. I`ve been amember of IEEE and its predecessors for 50 years and had a 1st phone ticket since April 1949. IEEE can manage no doubt less easily without ARRL.

Had there not been a useless code requirement, I likely would have had a ham ticket too 50 years ago too. I credit ARRL with my deprivation.

Best regards, Richard Harrison, KB5WZI

I agree with Gary, except for the voltage issue. Most catalogs I've
seen give a peak voltage breakdown, not RMS. 500 volts peak is 354
volts RMS, and that's 2500 watts peak or average power.

Most connectors are conservatively rated, and in a comntrolled
environment with a quality connector I'm not surprized to see an N
hadle 5 kW peak if average power is low and SWR is unity.

When dealing with arcing, peak and average power ratings are the same.
We should use RMS voltage only when heat is the concern, not arcing,
unless the component also uses RMS volage for the same waveshape.
Since component manufacturers can't control waveshape, they almost
always use peak voltage in ratings.

Despite the catalog numbers quoted, UHF connector fail at
considerably more voltage than N or BNC connectors....both of which
have about the same peak voltage flashover point.

The center pins in BNC and N's are almost identical, as are spacings.

The N connector and BNC connector have two weak areas compared to a
UHF connector. The UHF connector has much higher current handling
capacity and much higher voltage breakdown. I'd never use an N
connector in a high power (more than 1000 watts average) system unless
absolutely necessary for SWR reasons. At somewhere over 100 or 200 MHz
or for exceptionally critical applications , N connectors do have an
SWR advantage.

While all things are possible, the short answer is O'Hare. (tried to spell the Greek word for no phonetically, hope that was correct)The space transmissions must first be received by a high gain antenna with a low noise preamp. Next they must be converted to a frequency that falls with in the ability of the TV set to receive them.
What satellites are you trying to receive?

A one dB change in signal to noise ratio results in a great change in the amount of data recovered. You are trying to reccover data, not detect a volume change.

A one dB change in a clear single tone with no interference is the minimum discernable change in level for the average human.

When signals are close to noise (or interference) even less than 1 dB change can be quite noticable. When there is 20 dB of headroom, who cares?

Ed,
Bit late for that. It dealt with RFI. I've already been to court
twice, it's been resolved. The ARRL offered a list of attorneys that
was not current, information not applicable to the situation, a few
articles from QST (not submissable in court), and left me with a very
bad taste in my mouth.
If this was the only time that I was 'let down' by the ARRL I might
consider changing my mind about the organization, unfortunately, it
was only the latest instance. Thanks, but no thanks...
'Doc

Hi Tom--

Actually, the implication was supposed to be that I'm really just another alias--and a person so lazy and shiftless, it takes only 10 minutes a day for Chip to replicate my total output. Guess it didn't come off right.

Rick

Don't know about you, but I usually connect the feedline to my radio, then I pick the microphone when I talk or hang onto the key when I send. How far away does that place me?

Dear Roy and group:

Earlier this week I was helping a colleague set up laboratory jobs to help
EE students visualize and use transmission lines. Happened to have an OLD piece of RG11 some 25 meters long. The lower frequency limit of the instrumentation is 4 MHz. It was fascinating to see how the line parameters of the old piece (lossy) of coax change with frequency. At "low" frequency the surge impedance (Z0) was about 75 ohms, which, as the frequency was raised, proceeded to spiral around the 50 ohm center of the Smith chart. Yes, surge impedance can become reactive.
Heliax is quite uninteresting. 73 Mac
P.S. My AEA CIA was better at getting actual numbers than the very expensive piece of instrumentation. This is a neat time to work with electronics and RF. Using my GR RF bridge is a pain.

Source record: 181326

I thought Iï¿½d just add a little to the confusion. The antenna I am thinking of is a compromise upon a compromise. My 70-ft. tower is at the back of my small yard. The tower is 45 ft from by back door. It is 25 ft from the back property line and 35 and 45 ft from the side property lines. I have no other supports to use as the other end support for a classical dipole antenna, (no tall trees and the xyl would not stand for a structure in the front yard). Besides, 70 ft. is only a quarter wave above the ground on 80m anyway. An inverted Vee dipole is logical, except I donï¿½t have enough space to run one of the two legs without ending up in a neighborï¿½s yard. I donï¿½t want a vertical antenna and I donï¿½t expect to have a DX cannon either.

I am contemplating a distorted inverted Vee where one leg comes down relatively close to the tower while the other end can be run out to the front yard. The included angle will be a little less than 90 deg. between the legs. I can not feed this thing with open feed line because my ham shack is on the wrong side of the house and I have to thread my coax feed lines trough and around the crawl space.

I have an article from QST from the early 90s that talks about off-center feed dipoles. They were using them on multiple bands where they worked on even numbered harmonics of the fundamental resonance length. I only want to use it on one band. The two features I liked was keeping one leg short while getting a much wider bandwidth on 80/75m than a normal dipole.

Basically, you take a half wave wire cut for 3.75 MHz. and cut it in half so one leg is one third the total length and the other is two thirds the total length. I could keep the short leg close to the tower and run the long leg out to the front yard. This would keep the current maximum higher off the ground and would be more horizontally polarized. The feed point impedance was supposed to be about 300 ohms (for a flat dipole)(4 x 75 Ohms) with a 2:1 bandwidth that covered the whole band. In the inverted Vee config, I am guessing that the impedance will drop bringing it closer to 50 Ohms.

So I needed a 4:1 balun to do all of this.

I know that high SWR does not appreciably affect the efficiency of a dipole, and I do have a home brew antenna tuner that can handle the job. I just wanted to stay away from high SWR on the feed line in case I ever run a full 1.5 KW of power. I would not want the coax break down on me.

Actually, I goofed there. I was comparing for ten meters, but would
still act the same for 2m if at the same height in WL. Being the 2m
version would likely be much higher in WL, I'd expect a little higher
gain numbers and a little lower angles stated. MK

I was thinking of another good example of a vertical against a dipole...
My mobile antenna on my car. Houston to FLA I tested between my dipole
at 36 ft, and my car. The car won. And both only 100w . "Used the same
radio inside". I tested this a few more times to double check, but the
car won every time. The mobile ant was my 8 ft "plastic bugcatcher". 5
ft helical stick which was an old firestick cb ant, with a appx 2 inch
dia, 10-12 inch long homemade coil in the middle. A 3 ft "stinger" whip
on top. But a case of the antenna matching the angle that I needed to
make FLA. It's just right for that distance,and evidently the dipole
wasn't that good at that needed angle. So it would win even though in
reality it's much less efficient than the dipole. What it did do was at
the angle I wanted. This was fairly late at night. MK

Ian,

The most neglected subject in English engineers' education
is "Statistics". Next most neglected is "Economics".
Economy in time and material.

The whole of life, indeed the whole of existence, is
dominated by the laws of chance.

As a pedestrian you cross a busy road only because you have
subconsciously calculated a very high probability of
successfully arriving on the other side.

Baluns are needed for other engineering puposes than
prevention of TVI which, ststistically, they don't do. The
source of most TVI is the intentional high power radiation
from the main antenna and not from very weak accidental
stuff which *might* occur from other parts of the station.

The ONLY way of finding out whether a balun, by some small
chance, might be useful in keeping your TV-addicted XYL or
perhaps a neighbour happy, is not to fit one. It is clearly
uneconomical to fit one solely for that purpose and then to
test by removing it. If on its removal, as is most likely,
there is no TVI, would you put it back just because a
magazine article says it should always be there.

The engineering purpose of a balun is to transform from a
balanced to an unbalanced circuit in a transmitter
installation which conforms to licensing regulations. It is
NOT to cover up deficiencies (incompatiblities) in
television receivers which react unfavourably to frequencies
for which their owners are not licensed to receive.

The most economical way of curing TVI, in BOTH directions of
transmission, is to put a small choke in the TV mains power
lead or in the TV antenna down-lead immediately at the
receiver. Which most amateurs will take pleasure in making
and fitting for a neighbour entirely free of charge.

>Best regards, Richard Harrison, KB5WZI

My only encounter with this personally as a ham so far was interesting...
A friend asked me, "Mike aren't you worried about all this radio stuff
with all your high powered ham station and what they say about cell
phones?"

I said, "Well no, a simple explanation of this in how long the
antenna wire is! Mine are huge! You know 60 to 70 feet long!
The calculated the safe distance even with high power says I
can stand right near it safely!"

My friend's eyes widened a bit as I continued, Now as the antenna
gets shorter, things get worse. See that TV antenna, it's a *LOT*
shorter and smaller than my stuff you've seen! Getting next to a
TV transmitter may be a different story!"

I'd seen he was equipped!, Say! You have a cell phone on your belt!
Take it off and look at the length of the antenna! That's getting
short down toward the same short lengths you have in a microwave
oven, you know!"

Definite pause here in the conversation ...

My friend took up his phone, noticed the antenna was a little tiny thing!

He said, "Gee, but ny cell phone antenna is a little short
stubby thing. Does that mean it's worse than all your stuff
you are using?"

I grinned, "Could be! Remember you're holding it up next to your
ear all the time its in use! Course it's low power and we really
don't know! (Paused a moment) But maybe you're closer to the bad
stuff all the time than I am; you reckon?"

Friend has this puzzled look. He looks at me, then his cell phone, than
back at me. Now he's seen me with an HT, so he says, "But you use
something like a cell phone too!" His eyes are now all bright and beady

like!

I said, "Well yes, but as much as I use it, I also have a
hand mic on a cord so I don't hold it up to my head ....
just between us two pious and holy communicators here!"

Friend is now thinking realistically, maybe. At any rate he's not thinking the wrong things about ham radio! Score one for ham radio, no lies told, nothing wrong said. It's partly in how you say things that can help us all here.

There happens to be a very interesting article in the just arrived trade rag "CONFORMITY" for August 2000! Read the article "Medicinal EMF's" by Janet Raloff for a *VERY* interesting discussion of the medical effects on bone mass increase due to vibration!

It's put forth in the article that one reason that bone mass and strength increase as a result of vibration, is the bones are generating tiny EMF forces from piezo-electric effects that the shock of using them creates! Thus, it's being speculated that the proper use off EMF energy, in the right coupling mode to bones, EMF fields actually INCREASE their strength and decreases the effects of osteoporosis!

///
>O|O<
~

Now ... since reading that article, strictly in humor here .. if we all go around all this RF, is one reason we are so stubborn as hams, because our skulls have been hardened by all the bashing we take?

GDRFC ... again!

--> Sleep well; OS2's still awake! ;)

I am sorry to hear that. If the RFI problem involved the legal end of things, then that would have ended up with our Regulatory Information Branch. Once it becomes a legal matter, the League is rather limited in what it can do to help because the HQ staff is not qualified or licensed to give legal advice. The general help that can be given is to refer hams to those attorneys who have indicated to ARRL that they have some knowledge of ham radio and things RF and to offer some general information. Unfortunately, as attorneys move or leave practice, the League does not always know about the change, so the list can become a bit dated. I do appreciate any information about problems in the list that you forwarded when you discovered them; that information would have helped the next guy who had an RFI problem.

Over the past couple of months, a few things have changed. First, the Board just passed a motion that says in those cases where the Board believes that the case has strong national implications, the League can fund some of the legal expenses. I don't know how this will work out in practice.

The ARRL Web info on RFI and the law was updated quite a bit recently. See:

http://www.arrl.org/field/regulations/rfi-legal/

On that page, perhaps the most powerful information was written by an attorney and published in one of the collegiate legal journals. The link will get you to http://www.sbot.org/docs/RFI.pdf . Other good information are reprints of the various letters the FCC has written in support of federal pre-emption of RFI. I am certain that these would have been in the information that ARRL had sent to you (if not, the goof was bigger than I thought).

From the informational end, the FCC's information on RFI was rewritten a few years ago to be much more supportive of ham radio. (Tom Hora of the FCC led the team that did the rewrite; I forwarded to them nearly everything I had

ever written on RFI and told them they could use it shamelessly. The end result is pretty useful, thanks to the hard work of the FCC team.) The FCC info can be downloaded from:

http://www.fcc.gov/cib/Public_Notices/heee1.html

The ARRL TIS pages have a number of RFI pages, too. See http://www.arrl.org/tis/info/rfigen.html and follow the links. This information is continued in the ARRL RFI Book http://www.arrl.org/catalog/6834 .

Among the most important pages is the info for the neighbors of hams, published jointly by the ARRL and the Consumer Electronics Association. See http://204.245.190.45/tech_ed_and_training/resources/67-12005.cfm.

Would you mind sharing, either privately or on the appropriate NG, what your problem was, how it got resolved, what changes you think ARRL should make to its materials and what the League could have offered you that would have been helpful? Many of these cases are really not about RFI, or even RF safety, but are really related to the tower that your neighbors may not have liked. I can carry your feed back to the Regulatory folks and see what changes can be made to help others who may have the same problem. There have been a few changes made over the years, but there is always room for more improvement. (This is open to anyone; if you have any ideas on how the ARRL's material can be improved, send 'em on. If you have comments or input on ARRL policy, make your views known to your ARRL Director, see http://www.arrl.org/divisions for names, addresses, phone numbers, email addresses and URLs.)

What polarization? How does it reflect from the metal roof and house wiring?
Are the elements aluminum or copper? Sunspot cycle? What about worms next to
radials? yadayadayada

Now we get into arguments how to calculate, how to measure and looks like very
soon the solution is going to be - have a RF Gestapo running around with FS
meters or installing chart recorders at each station, and knock on your door
after midnight during the contest, ...
Never mind the "standard" is useless, based on nothing, but its the "law" so
obey by it or you will be taken to Siberia (where you will meet Freak - the
commandante of RF reeducation camp).
Stay away from RF, eat sugar and vegetarian crap and we will see you in SK
"honor" roll soon.

Yuri
the RF redneck

The TO angle is one of the most wasteful things included in any
modeling program. It causes more problems than it cures.

IMO, it is like "mismatch loss" on an antenna analyzer.

The only thing that matters for transmitting, in the general amateur
radio case where multipath isn't an issue, is the absolute gain at the
desired angle.

Forcing the TO angle lower for a given antenna height often reduces
the actual power at the distant location.

It is as foolish as looking for a deep single point null at the
expense of a broader but somewhat more shallow null.

Do the taste test Rick.

Place you tounge on the antenna, and transmit.

Now place you tounge on the microphone and see how it feels.

Better yet, do it the other way. The way I suggested above won't work,
becuase you woiuln't have a tounge left.

Now, if you want to carry this test in the next room....I guess it's
your choice. You might have your phil of things in that case.

Spark Ed! The FCC has ripped us of by not allowing us to use spark,
and it's all your fault!

Seriously, I'd like to see the ARRL ask for a narrow mode segment on
160 meters. One for RTTY, PSK, CW, and other narrow modes...just like
all the other bands have. If the ARRL did that, I'd support them like
they were the best thing since sliced butter!

Why does the ARRL think 160 is any different than the other bands from
80 through 2 meters?

A choke is the best things for power lines, but not antenna leads.

A series capacitor works better in antenna leads at the TV.

Actually the single most effective cure for TVI is shunting the common
mode current around the TV, rather than try to stop it. That works the
vast majorty of the time, and costs a few pennies.

From: Wayne Grauel <wgvideo@attglobal.net>
Message-ID: <39B82AC7.74B62794@attglobal.net>
Source record: 181347

OK Folks... here it goes. I have a 96 Suburban that I want to mount an antenna for 10 meters (without drilling holes in my vehicle). I currently made a mount from steel that comes out from under the rear bumper/drivers side (so doors will open). This antenna was a ham fest acquisition and the notation said it was very broad banded for 10 & 11 meters. it's shiny, has two big coils (like springs, not wound coils) and is about 5 feet tall or so and aparently isn't worth a hoot!. I have no directions. When mounted it sticks up past the roof about 1.5 maybe 2 feet. I took my TS440SAT out and placed it on the fron seat (coax is in the vehicle, not running outside).
SWR's were through the roof. The vehicle was sitting beside the house in the driveway.

I have a hunch this is a glorified CB antenna. The AT would tune it but not above 29 MHZ. I'd kinda like to have an antenna that will tune to a reasonable SWR so I can use my little IC706 (no tuner) .

Well everyone, did I give you enough info to point me in the right direction, do I start cutting wire off the antenna (whip is adjustable), or do I shit-can it and find a ham stick.
It is adjustable to about 4 inches before it bottoms out.

Inclusion.... here's a thought, does anyone think that by removing one of the sets of "springs" this would place it in the 10 meter band????
I'm assuming a 10 meter antenna will be shorter than an 11 meter antenna...no?

Back to original post....

I'm just not sure which way to go or what is the culprit.

I'd really like to stay with a bumber mount of some kind and not have some huge mast on top of the roof, etc.

Forget it, it's CB'er eye candy. The two springs are loading coils to tune it for use in the 11 meter band. As for being able to operate both 11 and 10 meters with a 5 foot antenna.. forget that also! The very best antenna for 10 meters is a simple stanless steel 108 inch whip from Radio Shack. Without the heavy spring it's just right to use on 10 meters. With the spring it's just right for 11 meters. You really don't need the spring with the antenna and an antenna tuner will match it for use on both bands. This is a simple 1/4 wave antenna and so no loading inductors are required and the match will be very close to 50 ohms also.

Source record: 181352

To model, for example, a dipole fed with coaxial line and no balun, just connect one side of the dipole center down to ground via a conductor of same length and diameter as the coaxial outer. Connect the generator to the dipole center.

The antenna doesn't know or care where the generator is situated. It receives its energy at the usual place and radiates it with a little assistance from the outer conductor of the coax. The computed radiation pattern will be correct.

But if you are interested in the input impedance of the coax it will have to be measured or calculated separately. Use one of my programs. DIPOLE1 does the obvious. RJELINE3 calculates the general case of input impedance of any impedance line for any terminating impedance. Program ZL_Zin does the reverse and calculates what the terminating impedance must be for a known input impedance (measured with your antenna analyser ?).

I'm not convinced Tom's soil is poor from a conductivity point of view. Hm, an idea. In your spare time, Tom, if you have the measurement equipment, you might run a radial measurement or two and determine the apparent conductivity like the broadcasters do. 160 is close enough to the AM BC band so the measurements should be reasonably valid.

Wonder how high the water table is where you live, Tom? At 1.8 MHz, the skin depth is 7 feet in very good soil, and nearly 20 feet in average soil. In poor soil it's 37 feet, so what's down deep gets more and more important as the soil gets poorer and poorer.

Maybe the disparity between Ed's models and Tom's observations is evidence that the arrival angle is lower, perhaps much lower, than the fairly high angle quoted by Ed. Does anyone know of any decent study or studies that actually determined "typical" arrival angles for really long-haul DX on or near 160 meters?

Ed, at what elevation angle are the vertical and dipole about equal, say over very good ground?

Hello Group,

Once upon a time, many moons ago, I used to have a really neat Log
Periodic antenna design program. The program was in Basic, and the
computer was an old XT. The old XT is long gone, along with the program,
I had a ball with that program and could design all kinds of
the things. Both the sloping wire, and the beam type.

Is there a version that will work with my latest confuser (computer),
with Windows 98?

1438. Antenna on a telephone pole

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-08 02:30:58 UTC
From: Bill <bill@hovac.com>
Message-ID: <8p9iuh$1sv9$1@box6.cho.cstone.net>
Source record: 181354

Hi All,
I have a telephone pole that is approximately 45ft high. I am planning on putting up a 10-15-20 tribander with a 18ft boom and a rotor.

Has anyone seen an antenna and rotor like this mounted on top of a couple of lengths of conduit on the ground and pulled up next to the pole with a rope or cable ? Seems to me it could be done, but would like some feedback from anyone who may have tried to help find glitches in it before I try it (or not).

Thanks,
Bill

Spare time, OK!

Actually I looked at the proof for WBAF on 1090. They did a radial
that crosses mu place. It looks like most areas around here at about 4
to 5 mS/m or so on 1090.

>Wonder how high the water table is where you live, Tom? At 1.8 MHz, the

It used to be high. My well is 30 feet deep, and I three springs on my
farm. They have gone dry, and the soil is bone dry now to ten feet or
so becuase of the drought. I still notice no difference.

>Maybe the disparity between Ed's models and Tom's observations is

>fairly high angle quoted by Ed. Does anyone know of any decent study or
>studies that actually determined "typical" arrival angles for really
>long-haul DX on or near 160 meters?

I can say this. My verticals work best for transmitting and receiving.

If I drop my dipoles, and feed the 318 foot tower as a vertical, it
remains good at night out at 500 miles or so. The 200 foot tower is
better closer in, and equal out far.

The 300 ft tower has a definite advantage during the daytime, working
long distances, over other omni antennas. The high dipole stinks
during the daytime. At night, there are times the dipole and 200 ft
vertical are even...but most of the time the vertical is best. The
vertical is never worse, not even inside Georgia.

I found this educational, but I wish the education came before I
installed the high tower. I really though a dipole antenna at 300 feet
or so, or a pair of dipoles phased, would be a killer antenna.

Now I'm educated.

So please someone, tell me what to do. I'd like to use that tall tower on 160, instead as a roost for Buzzards.

By the way, I hope with some help to be able to work out how to measure wave angle. I'm doing digital recordings of DX stations using a pair of phase locked receivers on two directional arrays antennas spaced about one wavelength apart.

73 Tom

Indeed! You have a future in politics, especially politics of the local, "law-and-order" {sic} variety. Ever know anyone, any community/city/county, to get excited and busy because the streets are safe and clean, the schools are graduating merit scholars, and property values are rising?

I have the QST CD-ROMs, and it is my opinion, having read articles, letters and editorials reaching back to the 20's, that have are no different than everyone else--we have been predicting our own demise, or else that ham radio is going to lose everything worthwhile about it, due to government/business taking our bands, new operators, new modes, new equipment, licensing changes, rules changes, equipment prices, and other technology since we got back on the air a few years after WWI.

It is really remarkable how little has changed since then--the tone, the arguments, the evidence, it's all virtually the same today as it was when H.P. Maxim was still ARRL President. I guess that we just aren't happy unless we can view ourselves as being under siege. Ever read or see Vonnegut's "Harrison Bergeron"? Like that, at the end.

Is this YOUR utility pole? If it is, but it is still in the utility
company's right of way it would not be legal for you to use it IMHO.

I wasn't convinced either, but when I ran the model over very good ground, all I saw was an improvement in the lowest angle performance, and a very slight decrease at the higher angles, just what I would have expected, with a slight increase in maximum gain at the lower angles.

Tom's results indicated that the vertical was better for even moderately close signals, if I recall what he said. If the vertical was over very good ground, I would expect to see that improvement only for signals arriving below 20 degrees.

I know of no studies, although I recall seeing a table published somewhere. To obtain such info, I usually use the absolutely incredible "IONCAP/WINDOWS" based program available as freeware at:

http://elbert.its.bldrdoc.gov/pc_hf/hfwin32.html

It is, btw, a 5 Mb file, so the download can be pretty slow. This version does NOT run on Windows 3.x; there are 16-bit verisons on the site. (/hfwin16.html?)

I just ran the ICEPAK program in the suite and after I entered a minimum angle of 5 degrees (seemed reasonable to me), it predicted the following angles:

http://www.arrl.org/~ehare/temp/angles.jpg

The SNR is shown at:

http://www.arrl.org/~ehare/temp/snr.jpg

Note that the angles are only good while the SNR is reasonable. SNR looks a bit low to me, but I did select residential noise instead of rural quiet.

In case anyone would like a brief glimpse of the user interface for ICEPAK, see:

http://www.arrl.org/~ehare/temp/icepak.jpg

> Ed, at what elevation angle are the vertical and dipole about equal, say
> over very good ground?

Oh, you had to ask, after I didn't save my working files. Okay, I will do it again. The results of the two antennas over very good ground are shown at:

http://www.arrl.org/~ehare/temp.compare.jpg

I can't explain Tom's results through modeling, but he is a capable and qualified ham who has put a lot of effort into his testing. OTOH, the results I am getting appear to be consistent with what I would expect from theory for verticals and horizontal dipoles. I did not do my dipole model "droopy," but I don't expect that would make a lot of difference. I also tossed the tower into the model, but saw no real difference. Now, I didn't take much pains to get the model exact, and didn't do any convergence, but for the number of segments, I think I was okay. I wonder if there are any other antennas nearby that are affecting the dipole more than the vertical, because the models say that the dipole should outperform the vertical almost all the time, sometimes by quite a bit.

Tom, is the SWR bandwidth of the dipole about what you would expect to see? Could there be some feed-line losses that could explain the differences? I sure hate it when models don't agree with someone's reality; I rely on models a lot. :-)

BTW, it is late, so if I got any of the URLs wrong, give me what-for tomorrow and I will post a correction. I will clean out that ~ehare/temp area in a few days, so if they are gone, it is too late. Now, at 11:29, it is time to really go home. GN, all.

You wouldn't take a Collins 30-T (circa 1931)? Just kidding you. I would go for both. Gimme an SW-3 (the king of bloopers!) *and* a a 6L6 xtal rig, or better an 813 rig & VFO. Also, I would like a pre-WWI Marconi receiver, and a working spark TX please! I finally found a pristine Radiola III I could afford, so the appeal of the <1930 radio world is no longer abstract for me. Now, if they could just discover a *huge* cache of NOS 01A's, 10's, and 45's so their price could come down within reach, then I'd be satisified. I am just barely old enough to remember Radio Row on Rector St. (or was it Church Street?) in lower Manhattan. My dad took me there a few times (we had [still do] an SX-62 that kept blowing its output tube every month) the year before they kicked them all out to build the WTC. I remember the glow of tubes, and that tube smell, and the static and 'hets that warbled as the salesman turned the VFO knob. I went 'ooooh' and 'ahhhhh', and I still do, more than ever, now that I have my own toys and know how they work and how to work them. It took me 25 years between those days in the aisles of Barry Electronics, and the others, and getting my first ticket (though I was a *serious* SWL for many years, got a new R-7 for Christmas in 1977. It replaced my SPR-4, which replaced my SX-110, which replaced my NC-33, which my dad got me so I would leave his SX-62 alone), but that just shows you the hold that radio has on some of us.

I'd go this route myself. I'd stick with the center fed dipole, no matter how contorted, and coax feed, which you prefer anyway. If the tower effects the tuning of the dipole, just slightly vary the center point a few inches, and it should tune up. Or just move the legs around a bit until you get a better match. You'd have to try adding to one end or the other to find the best match. I'd fear increased TVI etc problems from the OCF antennas. But the dipole would be pretty much a single band antenna unless you added other legs, or went with a tuner elsewhere from 80m. Or managed to feed with twin lead and a tuner someway. MK

The currents in the balanced feeder are designed to be balanced in the balanced 102ft G5RV physical dipole. Therefore, the balanced feeder is not supposed to radiate. Since modeling assumes balanced currents for balanced antennas, the model will not show feedline radiation. If there is feedline radiation, it is because of the environmental boundary conditions, something that most models don't handle very well, if at all.

It is current imbalance that causes feedline radiation and that will NOT happen when modeling balanced antennas with balanced feedlines.

Of course I can say that. It has worked for *ALL* my antennas. The only
requirement is that the 450 ohm SWR be between 4.5:1 and 18:1 and it
has been for all the antennas I have installed. Very few antennas don't
have a 450 ohm SWR between 4.5:1 and 18:1

What bandwidth should one expect to get with a
3 element yagi for 6 meters, using 7/8 tubing for
the elements and 44" spacing between, and using
1.7 to 1 as the SWR bandwith. Gamma match.
I'm getting very close to 1 MHZ, but I'm not
pleased with my mechanical design and will be
re-working things. I really hoped for the 2 mhz
another ham thought I could obtain, but I feel that
is unrealistic.
